

**HUMAN CDNAS AND PROTEINS AND USES THEREOF****DESCRIPTION**

5

**RELATED APPLICATIONS**

The present application claims priority from U.S. Patent Application Serial No. 09/924,340, filed August 6, 2001; International Patent Application Filing No. PCT/IB01/01715, filed August 6, 2001; U.S. Provisional Application Serial No. 60/305,456, filed July 13, 2001; and U.S. Provisional Application Serial No. 60/302,277, filed June 29, 2001, the disclosures of which  
10 are incorporated herein by reference in their entireties.

**FIELD OF THE INVENTION**

The present invention is directed to GENSET polypeptides, fragments thereof, and the regulatory regions located in the 5'- and 3'-ends of the genes encoding the polypeptides. The invention also concerns polypeptides encoded by GENSET polynucleotides and fragments thereof.  
15 The present invention also relates to recombinant vectors including the polynucleotides of the present invention, particularly recombinant vectors comprising a GENSET gene regulatory region or a sequence encoding a GENSET polypeptide, and to host cells containing the polynucleotides of the invention, as well as to methods of making such vectors and host cells. The present invention further relates to the use of these recombinant vectors and host cells in the production of the  
20 polypeptides of the invention. The invention further relates to antibodies that specifically bind to the polypeptides of the invention and to methods for producing such antibodies and fragments thereof. The invention also provides for methods of detecting the presence of the polynucleotides and polypeptides of the present invention in a sample, methods of diagnosis and screening of abnormal GENSET polypeptide expression and/or biological activity, methods of screening  
25 compounds for their ability to modulate the activity or expression of the GENSET polypeptides, and uses of such compounds.

**BACKGROUND OF THE INVENTION**

cDNAs encoding secreted proteins or fragments thereof represent a particularly valuable source of therapeutic agents. Thus, there is a need for the identification and characterization of  
30 secreted proteins and the nucleic acids encoding them.

In addition to being therapeutically useful themselves, secretory proteins include short peptides, called signal peptides, at their amino termini which direct their secretion. These signal peptides are encoded by the signal sequences located at the 5' ends of the coding sequences of genes encoding secreted proteins. Because these signal peptides will direct the extracellular  
35 secretion of any protein to which they are operably linked, the signal sequences may be exploited to direct the efficient secretion of any protein by operably linking the signal sequences to a gene encoding the protein for which secretion is desired. In addition, fragments of the signal peptides called membrane-translocating sequences may also be used to direct the intracellular import of a

peptide or protein of interest. This may prove beneficial in gene therapy strategies in which it is desired to deliver a particular gene product to cells other than the cells in which it is produced. Signal sequences encoding signal peptides also find application in simplifying protein purification techniques. In such applications, the extracellular secretion of the desired protein greatly facilitates  
5 purification by reducing the number of undesired proteins from which the desired protein must be selected. Thus, there exists a need to identify and characterize the 5' fragments of the genes for secretory proteins which encode signal peptides.

Sequences coding for secreted proteins may also find application as therapeutics or diagnostics. In particular, such sequences may be used to determine whether an individual is likely  
10 to express a detectable phenotype, such as a disease, as a consequence of a mutation in the coding sequence for a secreted protein. In instances where the individual is at risk of suffering from a disease or other undesirable phenotype as a result of a mutation in such a coding sequence, the undesirable phenotype may be corrected by introducing a normal coding sequence using gene therapy. Alternatively, if the undesirable phenotype results from overexpression of the protein  
15 encoded by the coding sequence, expression of the protein may be reduced using antisense or triple helix based strategies.

The secreted human polypeptides encoded by the coding sequences may also be used as therapeutics by administering them directly to an individual having a condition, such as a disease, resulting from a mutation in the sequence encoding the polypeptide. In such an instance, the  
20 condition can be cured or ameliorated by administering the polypeptide to the individual.

In addition, the secreted human polypeptides or fragments thereof may be used to generate antibodies useful in determining the tissue type or species of origin of a biological sample. The antibodies may also be used to determine the cellular localization of the secreted human polypeptides or the cellular localization of polypeptides which have been fused to the human  
25 polypeptides. In addition, the antibodies may also be used in immunoaffinity chromatography techniques to isolate, purify, or enrich the human polypeptide or a target polypeptide which has been fused to the human polypeptide.

#### **SUMMARY OF THE INVENTION**

The present invention provides a purified or isolated polynucleotide comprising, consisting  
30 of, or consisting essentially of a nucleotide sequence selected from the group consisting of: (a) the sequences of the **odd** SEQ ID NOs:1-111; (b) the sequences of clone inserts of the deposited clone pool; (c) the coding sequences of the odd SEQ ID NOs:1-111; (d) the coding sequences of the clone inserts of the deposited clone pool; (e) the sequences encoding one of the polypeptides of the **even** SEQ ID NOs:2-112; (f) the sequences encoding one of the polypeptides encoded by the clone  
35 inserts of the deposited clone pool; (g) the genomic sequences coding for the GENSET polypeptides; (h) the 5' transcriptional regulatory regions of GENSET genes; (i) the 3' transcriptional regulatory regions of GENSET genes; (j) the polynucleotides comprising the

polypeptides having an amino acid sequence at least 70% identical, more preferably at least 75% identical, and still more preferably 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% identical to those polypeptides described in (a)-(i), or fragments thereof, e.g. over a region of amino acids at least any one integer between 6 and the last integer representing the last amino acid of a specified polypeptide sequence of the sequence listing. The invention further relates to methods of making the polypeptides of the present invention.

The present invention further relates to transgenic plants or animals, wherein said transgenic plant or animal is transgenic for a polynucleotide of the present invention and expresses a polypeptide of the present invention.

10 The invention further relates to antibodies that specifically bind to GENSET polypeptides of the present invention and fragments thereof as well as to methods for producing such antibodies and fragments thereof.

The invention also provides kits, uses and methods for detecting GENSET gene expression and/or biological activity in a biological sample. One such method involves assaying for the expression of a GENSET polynucleotide in a biological sample using the polymerase chain reaction (PCR) to amplify and detect GENSET polynucleotides or Southern and Northern blot hybridization to detect GENSET genomic DNA, cDNA or mRNA. Alternatively, a method of detecting GENSET gene expression in a test sample can be accomplished using a compound which binds to a GENSET polypeptide of the present invention or a portion of a GENSET polypeptide.

20 The present invention also relates to diagnostic methods and uses of GENSET polynucleotides and polypeptides for identifying individuals or non-human animals having elevated or reduced levels of GENSET gene products, which individuals are likely to benefit from therapies to suppress or enhance GENSET gene expression, respectively, and to methods of identifying individuals or non-human animals at increased risk for developing, or at present having, certain diseases/disorders associated with GENSET polypeptide expression or biological activity.

The present invention also relates to kits, uses and methods of screening compounds for their ability to modulate (e.g. increase or inhibit) the activity or expression of GENSET polypeptides including compounds that interact with GENSET gene regulatory sequences and compounds that interact directly or indirectly with a GENSET polypeptide. Uses of such compounds are also within the scope of the present invention.

The present invention also relates to pharmaceutical or physiologically acceptable compositions comprising, an active agent, the polypeptides, polynucleotides or antibodies of the present invention, as well as, typically, a physiologically acceptable carrier.

35 The present invention also relates to computer systems containing cDNA codes and polypeptide codes of sequences of the invention and to computer-related methods of comparing sequences, identifying homology or features using GENSET polypeptides or GENSET

polynucleotide sequences of the invention.

In another aspect, the present invention provides an isolated polynucleotide, the polynucleotide comprising a nucleic acid sequence encoding a polypeptide of the present invention including the polypeptide of (a) through (i) above.

- 5 In another aspect, the present invention provides a non-human transgenic animal comprising the host cell.

In another aspect, the present invention provides a method of making a GENSET polypeptide, the method comprising a) providing a population of host cells comprising a herein-described polynucleotide and b) culturing the population of host cells under conditions conducive  
10 to the production of the polypeptide within said host cells.

In one embodiment, the method further comprises purifying the polypeptide from the population of host cells.

In another aspect, the present invention provides a method of making a GENSET polypeptide, the method comprising a) providing a population of cells comprising a polynucleotide  
15 encoding a herein-described polypeptide; b) culturing the population of cells under conditions conducive to the production of the polypeptide within the cells; and c) purifying the polypeptide from the population of cells.

In another aspect, the present invention provides a biologically active polypeptide encoded by any of the herein-described polynucleotides.

- 20 In one embodiment, the polypeptide is selectively recognized by an antibody raised against an antigenic polypeptide, or an antigenic fragment thereof, the antigenic polypeptide comprising any one of the sequences shown as even SEQ ID NOs:2-112 or any one of the sequences of polypeptides encoded by the human cDNAs of the deposited clone pool.

In another aspect, the present invention provides an antibody that specifically binds to any  
25 of the herein-described polypeptides and methods of binding antibody to said polypeptide.

In another aspect, the present invention provides a method of determining whether a GENSET gene is expressed within a mammal, the method comprising the steps of: a) providing a biological sample from said mammal; b) contacting said biological sample with either of: (i) a polynucleotide that hybridizes under stringent conditions to any of the herein-described  
30 polynucleotides; or (ii) a polypeptide that specifically binds to any of the herein-described polypeptides; and c) detecting the presence or absence of hybridization between the polynucleotide and an RNA species within the sample, or the presence or absence of binding of the polypeptide to a protein within the sample; wherein a detection of the hybridization or of the binding indicates that the GENSET gene is expressed within the mammal.

- 35 In one embodiment, the polynucleotide is a primer, and the hybridization is detected by detecting the presence of an amplification product comprising the sequence of the primer. In another embodiment, the polypeptide is an antibody.

In another aspect, the present invention provides a method of determining whether a mammal has an elevated or reduced level of GENSET gene expression, the method comprising the steps of: a) providing a biological sample from the mammal; and b) comparing the amount of any of the herein-described polypeptides, or of an RNA species encoding the polypeptide, within the biological sample with a level detected in or expected from a control sample; wherein an increased amount of the polypeptide or the RNA species within the biological sample compared to the level detected in or expected from the control sample indicates that the mammal has an elevated level of the GENSET gene expression, and wherein a decreased amount of the polypeptide or the RNA species within the biological sample compared to the level detected in or expected from the control sample indicates that the mammal has a reduced level of the GENSET gene expression.

In another aspect, the present invention provides a method of identifying a candidate modulator of a GENSET polypeptide, the method comprising: a) contacting any of the herein-described polypeptides with a test compound; and b) determining whether the compound specifically binds to the polypeptide; wherein a detection that the compound specifically binds to the polypeptide indicates or inhibits or activates of a specified biological activity that the compound is a candidate modulator of the GENSET polypeptide.

#### **BRIEF DESCRIPTION OF DRAWINGS**

Figure 1 is a block diagram of an exemplary computer system.

Figure 2 is a flow diagram illustrating one embodiment of a process 200 for comparing a new nucleotide or protein sequence with a database of sequences in order to determine the identity levels between the new sequence and the sequences in the database.

Figure 3 is a flow diagram illustrating one embodiment of a process 250 in a computer for determining whether two sequences are homologous.

Figure 4 is a flow diagram illustrating one embodiment of an identifier process 300 for detecting the presence of a feature in a sequence.

#### **BRIEF DESCRIPTION OF TABLES**

**Table I** provides the Applicants' internal designation number (Clone ID\_Clone Name) which corresponds to each sequence identification number (SEQ ID NO.) of the Sequence Listing, and indicates whether the sequence is a nucleic acid sequence (DNA) or a polypeptide sequence (PRT). Further provided is information regarding the name of the corresponding nucleic acid or polypeptide sequence, and information regarding the deposit of biological material. It should be appreciated that biological materials have been deposited with reference to their corresponding Clone ID, Clone Name, or both Clone ID\_Clone Name.

**Table II** provides the positions of the nucleotides of the corresponding SEQ ID NOs. of the Sequence Listing which comprise the open reading frame (ORF), signal peptide, mature peptide, polyadenylation signal, and the polyA tail of the polynucleotides of the invention.

**Table III** provides the positions of the amino acid of the corresponding SEQ ID NOs. of

the Sequence Listing which comprise the positions of immunogenic epitopes of the polypeptides of the invention, which are useful in antibody generation as described in Example 1.

**Table IV** provides the positions of the nucleotides comprising preferentially included or excluded fragments of the corresponding SEQ ID NOs. of the Sequence Listing.

5

#### **BRIEF DESCRIPTION OF SEQUENCES**

Sequences are presented in the accompanying Sequence Listing.

Odd SEQ ID NOs:1-111 are the nucleotide sequences of cDNAs, with open reading frames as indicated. When appropriate, the potential polyadenylation site and polyadenylation signal are also indicated.

10 Even SEQ ID NOs:2-112 are the amino acid sequences of proteins encoded by the cDNAs of odd SEQ ID NOs:1-111.

In accordance with the regulations relating to Sequence Listings, the following codes have been used in the Sequence Listing to describes nucleotide sequences. The code "r" in the sequences indicates that the nucleotide may be a guanine or an adenine. The code "y" in the sequences indicates that the nucleotide may be a thymine or a cytosine. The code "m" in the sequences indicates that the nucleotide may be an adenine or a cytosine. The code "k" in the sequences indicates that the nucleotide may be a guanine or a thymine. The code "s" in the sequences indicates that the nucleotide may be a guanine or a cytosine. The code "w" in the sequences indicates that the nucleotide may be an adenine or an thymine. In addition, all instances of the symbol "n" in the nucleic acid sequences mean that the nucleotide can be adenine, guanine, cytosine or thymine.

In some instances, the polypeptide sequences in the Sequence Listing contain the symbol "Xaa." These "Xaa" symbols indicate either (1) a residue which cannot be identified because of nucleotide sequence ambiguity or (2) a stop codon in the determined sequence where applicants believe one should not exist (if the sequence were determined more accurately). In some instances, several possible identities of the unknown amino acids may be suggested by the genetic code.

In the case of secreted proteins, it should be noted that, in accordance with the regulations governing Sequence Listings, in the appended Sequence Listing the encoded protein (i.e. the protein containing the signal peptide and the mature protein or fragment thereof) extends from an amino acid residue having a negative number through a positively numbered amino acid residue. Thus, the first amino acid of the mature protein resulting from cleavage of the signal peptide is designated as amino acid number 1, and the first amino acid of the signal peptide is designated with the appropriate negative number.

In the case that a polynucleotide or polypeptide sequence described in the specification for SEQ ID NOs:1-112 is in conflict with the corresponding sequence provided in the Sequence listing, the sequences provided in the Sequence listing controls.

It should be appreciated the the polynucleotide and polypeptide sequences of SEQ ID NO:1-112 of the Sequence Listing are hereby incorporated by reference in their entireties.

## **DETAILED DESCRIPTION OF THE INVENTION AND PREFERRED EMBODIMENTS**

### **Definitions.**

5 Before describing the invention in greater detail, the following definitions are set forth to illustrate and define the meaning and scope of the terms used to describe the invention herein.

The term "GENSET gene," when used herein, encompasses genomic, mRNA and cDNA sequences encoding a GENSET polypeptide, including the 5' and 3' untranslated regions of said sequences.

10 The term "GENSET polypeptide biological activity" or "GENSET biological activity" is intended for polypeptides exhibiting any activity similar, but not necessarily identical, to an activity of a GENSET polypeptide of the invention. The GENSET polypeptide biological activity of a given polypeptide may be assessed using any suitable biological assay, a number of which are known to those skilled in the art. In contrast, the term "biological activity" refers to any activity  
15 that any polypeptide may have.

The term "corresponding mRNA" refers to mRNA which was or can be a template for cDNA synthesis for producing a cDNA of the present invention.

The term "corresponding genomic DNA" refers to genomic DNA which encodes an mRNA of interest, e.g. corresponding to a cDNA of the invention, which genomic DNA includes  
20 the sequence of one of the strands of the mRNA, in which thymidine residues in the sequence of the genomic DNA (or cDNA) are replaced by uracil residues in the mRNA.

The term "deposited clone pool" is used herein to refer to the pool of clones entitled cDNA-11-2000 deposited with the ATCC on November 27, 2000, or cDNA-8-2000, deposited with the ATCC on September 15, 2000.

25 The term "heterologous", when used herein, is intended to designate any polynucleotide or polypeptide other than a GENSET polynucleotide or GENSET polypeptide of the invention, respectively.

"Providing" with respect to, e.g. a biological sample, population of cells, etc. indicates that the sample, population of cells, etc. is somehow used in a method or procedure. Significantly,  
30 "providing" a biological sample or population of cells does not require that the sample or cells are specifically isolated or obtained for the purposes of the invention, but can instead refer, for example, to the use of a biological sample obtained by another individual, for another purpose.

An "amplification product" refers to a product of any amplification reaction, e.g. PCR, RT-PCR, LCR, etc.

35 A "modulator" of a protein or other compound refers to any agent that has a functional effect on the protein, including physical binding to the protein, alterations of the quantity or quality of expression of the protein, altering any measurable or detectable activity, property, or behavior of the protein, or in any way interacts with the protein or compound.

"A test compound" can be any molecule that is evaluated for its ability to modulate a protein or other compound.

An antibody or other compound that specifically binds to a polypeptide or polynucleotide of the invention is also said to "selectively recognize" the polypeptide or polynucleotide.

5 The term "isolated" with respect to a molecule requires that the molecule be removed from its original environment (e. g., the natural environment if it is naturally occurring). For example, a naturally-occurring polynucleotide or polypeptide present in a living animal is not isolated, but the same polynucleotide or DNA or polypeptide, separated from some or all of the coexisting materials in the natural system, is isolated. Such polynucleotide could be part of a vector and/or such  
10 polynucleotide or polypeptide could be part of a composition, and still be isolated in that the vector or composition is not part of its natural environment. For example, a naturally-occurring polynucleotide present in a living animal is not isolated, but the same polynucleotide, separated from some or all of the coexisting materials in the natural system, is isolated. Specifically excluded from the definition of "isolated" are: naturally-occurring chromosomes (such as  
15 chromosome spreads), artificial chromosome libraries, genomic libraries, and cDNA libraries that exist either as an *in vitro* nucleic acid preparation or as a transfected/transformed host cell preparation, wherein the host cells are either an *in vitro* heterogeneous preparation or plated as a heterogeneous population of single colonies. Also specifically excluded are the above libraries wherein a specified polynucleotide makes up less than 5% (may also be specified as 10%, 25%,  
20 50%, or 75%) of the number of nucleic acid inserts in the vector molecules. Further specifically excluded are whole cell genomic DNA or whole cell RNA preparations (including said whole cell preparations which are mechanically sheared or enzymatically digested). Further specifically excluded are the above whole cell preparations as either an *in vitro* preparation or as a heterogeneous mixture separated by electrophoresis (including blot transfers of the same) wherein  
25 the polynucleotide of the invention has not further been separated from the heterologous polynucleotides in the electrophoresis medium (e.g., further separating by excising a single band from a heterogeneous band population in an agarose gel or nylon blot).

The term "purified" does not require absolute purity; rather, it is intended as a relative definition. Purification of starting material or natural material to at least one order of magnitude,  
30 preferably two or three orders, and more preferably four or five orders of magnitude is expressly contemplated.

The term "purified" is further used herein to describe a polypeptide or polynucleotide of the invention which has been separated from other compounds including, but not limited to, polypeptides or polynucleotides, carbohydrates, lipids, etc. The term "purified" may be used to  
35 specify the separation of monomeric polypeptides of the invention from oligomeric forms such as homo- or hetero- dimers, trimers, etc. The term "purified" may also be used to specify the separation of covalently closed (i.e. circular) polynucleotides from linear polynucleotides. A

substantially pure polypeptide or polynucleotide typically comprises about 50%, preferably 60 to 90% weight/weight of a polypeptide or polynucleotide sample, respectively, more usually about 95%, and preferably is over about 99% pure but, may be specified as any integer of percent between 50 and 100. Polypeptide and polynucleotide purity, or homogeneity, is indicated by a number of means well known in the art, such as agarose or polyacrylamide gel electrophoresis of a sample, followed by visualizing a single band upon staining the gel. For certain purposes higher resolution can be provided by using HPLC or other means well known in the art. As an alternative embodiment, purification of the polypeptides and polynucleotides of the present invention may be expressed as "at least" a percent purity relative to heterologous polypeptides and polynucleotides (DNA, RNA or both). As a preferred embodiment, the polypeptides and polynucleotides of the present invention are at least; 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, 96%, 96%, 98%, 99%, or 100% pure relative to heterologous polypeptides and polynucleotides, respectively. As a further preferred embodiment the polypeptides and polynucleotides have a purity ranging from any number, to the thousandth position, between 90% and 100% (e.g., a polypeptide or polynucleotide at least 99.995% pure) relative to either heterologous polypeptides or polynucleotides, respectively, or as a weight/weight ratio relative to all compounds and molecules other than those existing in the carrier. Each number representing a percent purity, to the thousandth position, may be claimed as individual species of purity.

As used interchangeably herein, the terms "nucleic acid molecule(s)", "oligonucleotide(s)", and "polynucleotide(s)" include RNA or DNA (either single or double stranded, coding, complementary or antisense), or RNA/DNA hybrid sequences of more than one nucleotide in either single chain or duplex form (although each of the above species may be particularly specified). The term "nucleotide" is used herein as an adjective to describe molecules comprising RNA, DNA, or RNA/DNA hybrid sequences of any length in single-stranded or duplex form. More precisely, the expression "nucleotide sequence" encompasses the nucleic material itself and is thus not restricted to the sequence information (i.e. the succession of letters chosen among the four base letters) that biochemically characterizes a specific DNA or RNA molecule. The term "nucleotide" is also used herein as a noun to refer to individual nucleotides or varieties of nucleotides, meaning a molecule, or individual unit in a larger nucleic acid molecule, comprising a purine or pyrimidine, a ribose or deoxyribose sugar moiety, and a phosphate group, or phosphodiester linkage in the case of nucleotides within an oligonucleotide or polynucleotide. The term "nucleotide" is also used herein to encompass "modified nucleotides" which comprise at least one modification such as (a) an alternative linking group, (b) an analogous form of purine, (c) an analogous form of pyrimidine, or (d) an analogous sugar. For examples of analogous linking groups, purine, pyrimidines, and sugars, see, for example, PCT publication No. WO 95/04064, which disclosure is hereby incorporated by reference in its entirety. Preferred modifications of the present invention include, but are not limited to, 5-fluorouracil, 5-bromouracil, 5-chlorouracil,

5-iodouracil, hypoxanthine, xantine, 4-acetylcytosine, 5-(carboxyhydroxymethyl) uracil, 5-carboxymethylaminomethyl-2-thiouridine, 5-carboxymethylaminomethyluracil, dihydrouracil, beta-D-galactosylqueosine, inosine, N6-isopentenyladenine, 1-methylguanine, 1-methylinosine, 2,2-dimethylguanine, 2-methyladenine, 2-methylguanine, 3-methylcytosine, 5-methylcytosine, 5 N6-adenine, 7-methylguanine, 5-methylaminomethyluracil, 5-methoxyaminomethyl-2-thiouracil, beta-D-mannosylqueosine, 5'-methoxycarboxymethyluracil, 5-methoxyuracil, 2-methylthio-N6-isopentenyladenine, uracil-5-oxyacetic acid (v) ybutoxosine, pseudouracil, queosine, 2-thiocytosine, 5-methyl-2-thiouracil, 2-thiouracil, 4-thiouracil, 5-methyluracil, uracil-5-oxyacetic acid methylester, uracil-5-oxyacetic acid, 5-methyl-2-thiouracil, 3-(3-amino-3-N-2-carboxypropyl) uracil, and 2,6-diaminopurine. The polynucleotide sequences of the invention may be prepared by any known method, including synthetic, recombinant, *ex vivo* generation, or a combination thereof, as well as utilizing any purification methods known in the art. Methylenemethylimino linked oligonucleosides as well as mixed backbone compounds having, may be prepared as described in U.S. Pat. Nos. 5,378,825; 5,386,023; 5,489,677; 5,602,240; and 5,610,289, which disclosures are hereby incorporated by reference in their entireties. Formacetal and thioformacetal linked oligonucleosides may be prepared as described in U.S. Pat. Nos. 5,264,562 and 5,264,564, which disclosures are hereby incorporated by reference in their entireties. Ethylene oxide linked oligonucleosides may be prepared as described in U.S. Pat. No. 5,223,618, which disclosure is hereby incorporated by reference in its entirety. Phosphinate oligonucleotides may be prepared as described in U.S. Pat. No. 5,508,270, which disclosure is hereby incorporated by reference in its entirety. Alkyl phosphonate oligonucleotides may be prepared as described in U.S. Pat. No. 4,469,863, which disclosure is hereby incorporated by reference in its entirety. 3'-Deoxy-3'-methylene phosphonate oligonucleotides may be prepared as described in U.S. Pat. Nos. 5,610,289 or 5,625,050 which disclosures are hereby incorporated by reference in their entireties. Phosphoramidite oligonucleotides may be prepared as described in U.S. Pat. No. 5,256,775 or U.S. Pat. No. 5,366,878 which disclosures are hereby incorporated by reference in their entireties. Alkylphosphonothioate oligonucleotides may be prepared as described in published PCT applications WO 94/17093 and WO 94/02499 which disclosures are hereby incorporated by reference in their entireties. 3'-Deoxy-3'-amino phosphoramidate oligonucleotides may be prepared as described in U.S. Pat. No. 5,476,925, which disclosure is hereby incorporated by reference in its entirety. Phosphotriester oligonucleotides may be prepared as described in U.S. Pat. No. 5,023,243, which disclosure is hereby incorporated by reference in its entirety. Borano phosphate oligonucleotides may be prepared as described in U.S. Pat. Nos. 5,130,302 and 5,177,198 which disclosures are hereby incorporated by reference in their entireties.

The term "upstream" is used herein to refer to a location which is toward the 5' end of the polynucleotide from a specific reference point.

The terms "base paired" and "Watson & Crick base paired" are used interchangeably

herein to refer to nucleotides which can be hydrogen bonded to one another by virtue of their sequence identities in a manner like that found in double-helical DNA with thymine or uracil residues linked to adenine residues by two hydrogen bonds and cytosine and guanine residues linked by three hydrogen bonds (see Stryer, (1995) Biochemistry, 4th edition, which disclosure is hereby incorporated by reference in its entirety).

The terms "complementary" or "complement thereof" are used herein to refer to the sequences of polynucleotides which is capable of forming Watson & Crick base pairing with another specified polynucleotide throughout the entirety of the complementary region. For the purpose of the present invention, a first polynucleotide is deemed to be complementary to a second polynucleotide when each base in the first polynucleotide is paired with its complementary base. Complementary bases are, generally, A and T (or A and U), or C and G. "Complement" is used herein as a synonym from "complementary polynucleotide", "complementary nucleic acid" and "complementary nucleotide sequence". These terms are applied to pairs of polynucleotides based solely upon their sequences and not any particular set of conditions under which the two polynucleotides would actually bind. Unless otherwise stated, all complementary polynucleotides are fully complementary on the whole length of the considered polynucleotide.

The terms "polypeptide" and "protein", used interchangeably herein, refer to a polymer of amino acids without regard to the length of the polymer; thus, peptides, oligopeptides, and proteins are included within the definition of polypeptide. This term also does not specify or exclude chemical or post-expression modifications of the polypeptides of the invention, although chemical or post-expression modifications of these polypeptides may be included or excluded as specific embodiments. Therefore, for example, modifications to polypeptides that include the covalent attachment of glycosyl groups, acetyl groups, phosphate groups, lipid groups and the like are expressly encompassed by the term polypeptide. Further, polypeptides with these modifications may be specified as individual species to be included or excluded from the present invention. The natural or other chemical modifications, such as those listed in examples above can occur anywhere in a polypeptide, including the peptide backbone, the amino acid side-chains and the amino or carboxyl termini. It will be appreciated that the same type of modification may be present in the same or varying degrees at several sites in a given polypeptide. Also, a given polypeptide may contain many types of modifications. Polypeptides may be branched, for example, as a result of ubiquitination, and they may be cyclic, with or without branching. Modifications include acetylation, acylation, ADP-ribosylation, amidation, covalent attachment of flavin, covalent attachment of a heme moiety, covalent attachment of a nucleotide or nucleotide derivative, covalent attachment of a lipid or lipid derivative, covalent attachment of phosphatidylinositol, cross-linking, cyclization, disulfide bond formation, demethylation, formation of covalent cross-links, formation of cysteine, formation of pyroglutamate, formylation, gamma-carboxylation, glycosylation, GPI anchor formation, hydroxylation, iodination,

methylation, myristoylation, oxidation, pegylation, proteolytic processing, phosphorylation, prenylation, racemization, selenoylation, sulfation, transfer-RNA mediated addition of amino acids to proteins such as arginylation, and ubiquitination. [See, for instance Creighton, (1993), Posttranslational Covalent Modification of Proteins, W.H. Freeman and Company, New York B.C. Johnson, Ed., Academic Press, New York 1-12; Seifter, *et al.*, (1990) Meth Enzymol 182:626-646; Rattan *et al.*, (1992) Ann NY Acad Sci 663:48-62]. Also included within the definition are polypeptides which contain one or more analogs of an amino acid (including, for example, non-naturally occurring amino acids, amino acids which only occur naturally in an unrelated biological system, modified amino acids from mammalian systems, etc.), polypeptides with substituted linkages, as well as other modifications known in the art, both naturally occurring and non-naturally occurring.

As used herein, the terms "recombinant polynucleotide" and "polynucleotide construct" are used interchangeably to refer to linear or circular, purified or isolated polynucleotides that have been artificially designed and which comprise at least two nucleotide sequences that are not found as contiguous nucleotide sequences in their initial natural environment. In particular, these terms mean that the polynucleotide or cDNA is adjacent to "backbone" nucleic acid to which it is not adjacent in its natural environment. Additionally, to be "enriched" the cDNAs will represent 5% or more of the number of nucleic acid inserts in a population of nucleic acid backbone molecules. Backbone molecules according to the present invention include nucleic acids such as expression vectors, self-replicating nucleic acids, viruses, integrating nucleic acids, and other vectors or nucleic acids used to maintain or manipulate a nucleic acid insert of interest. Preferably, the enriched cDNAs represent 15% or more of the number of nucleic acid inserts in the population of recombinant backbone molecules. More preferably, the enriched cDNAs represent 50% or more of the number of nucleic acid inserts in the population of recombinant backbone molecules. In a highly preferred embodiment, the enriched cDNAs represent 90% or more (including any number between 90 and 100%, to the thousandth position, e.g., 99.5%) of the number of nucleic acid inserts in the population of recombinant backbone molecules.

The term "recombinant polypeptide" is used herein to refer to polypeptides that have been artificially designed and which comprise at least two polypeptide sequences that are not found as contiguous polypeptide sequences in their initial natural environment, or to refer to polypeptides which have been expressed from a recombinant polynucleotide.

As used herein, the term "operably linked" refers to a linkage of polynucleotide elements in a functional relationship. A sequence which is "operably linked" to a regulatory sequence such as a promoter means that said regulatory element is in the correct location and orientation in relation to the nucleic acid to control RNA polymerase initiation and expression of the nucleic acid of interest. For instance, a promoter or enhancer is operably linked to a coding sequence if it affects the transcription of the coding sequence.

The term "domain" refers to an amino acid fragment with specific biological properties. This term encompasses all known structural and linear biological motifs. Examples of such motifs include but are not limited to leucine zippers, helix-turn-helix motifs, glycosylation sites, ubiquitination sites, alpha helices, and beta sheets, signal peptides which direct the secretion of proteins, sites for post-translational modification, enzymatic active sites, substrate binding sites, and enzymatic cleavage sites.

Although each of these terms has a distinct meaning, the terms "comprising", "consisting of" and "consisting essentially of" may be interchanged for one another throughout the instant application. The term "having" has the same meaning as "comprising" and may be replaced with either the term "consisting of" or "consisting essentially of".

Unless otherwise specified in the application, nucleotides and amino acids of polynucleotides and polypeptides, respectively, of the present invention are contiguous and not interrupted by heterologous sequences.

The term "neoplastic cells" as used herein refers to cells that result from abnormal new growth. A neoplastic cell further includes transformed cells, cancer cells including blood cancers and solid tumors (benign and malignant).

As used herein, the term "tumor" refers to an abnormal mass or population of cells that result from excessive cell division, whether malignant or benign, and all pre-cancerous and cancerous cells and tissues. A "tumor" is further defined as two or more neoplastic cells.

"Malignant tumors" are distinguished from benign growths or tumors in that, in addition to uncontrolled cellular proliferation, they will invade surrounding tissues and may additionally metastasize.

The term "transformed cells," "malignant cells" or "cancer" are interchangeable and refer to cells that have undergone malignant transformation, but may also include lymphocyte cells that have undergone blast transformation. Malignant transformation is a conversion of normal cells to malignant cells. Transformed cells have a greater ability to cause tumors when injected into animals. Transformation can be recognized by changes in growth characteristics, particularly in requirements for macromolecular growth factors, and often also by changes in morphology. Transformed cells usually proliferate without requiring adhesion to a substratum and usually lack cell to cell inhibition and pile up after forming a monolayer in cell culture.

The term "neoplastic disease" as used herein refers to a condition characterized by uncontrolled, abnormal growth of cells. Neoplastic diseases include cancer. Examples of cancer include but are not limited to, carcinoma, lymphoma, blastoma, sarcoma, and leukemia. More particular examples of such cancers include breast cancer, prostate cancer, colon cancer, squamous cell cancer, small-cell lung cancer, non-small cell lung cancer, ovarian cancer, cervical cancer, gastrointestinal cancer, pancreatic cancer, glioblastoma, liver cancer, bladder cancer, hepatoma, colorectal cancer, uterine cervical cancer, endometrial carcinoma, salivary gland carcinoma,

kidney cancer, vulval cancer, thyroid cancer, hepatic carcinoma, skin cancer, melanoma, brain cancer, ovarian cancer, neuroblastoma, myeloma, various types of head and neck cancer, acute lymphoblastic leukemia, acute myeloid leukemia, Ewing sarcoma and peripheral neuroepithelioma. All of the possible cancers listed herein are included in, or may be excluded from, the present invention as individual species.

As used herein, the term "carcinoma" refers to a new growth that arises from epithelium, found in skin or, more commonly, the lining of body organs (adenocarcinoma), for example: breast, prostate, lung, stomach or bowel. Carcinomas include bladder carcinoma, hepatocarcinoma, hepatoblastoma, rhabdomyosarcoma, ovarian carcinoma, cervical carcinoma, lung carcinoma, breast carcinoma, colorectal carcinoma, uterine cervical cancer carcinoma, endometrioid carcinoma, paraganglioma, squamous cell carcinoma in head and neck, esophageal carcinoma, thyroid carcinoma, astrocytoma, neuroblastoma and neuroepithelioma. All of the possible carcinomas listed herein are included in, or may be excluded from, the present invention as individual species.

The term "immortalized cells" as used herein refers to cells reproduce indefinitely. The cells escape from the normal limitation on growth of a finite number of division cycles. The term does not include malignant cells.

The term "normal cells" as used herein refers to cells that have a limitation on growth, i.e. a finite number of division cycles (the Hayflick limit); therefore, is a nontumorigenic cell. Normal cell include primary cells, which is a cell or cell line taken directly from a living organism which is not immortalized.

The term "cell cycle" as used herein refers to the cyclic biochemical and structural events occurring during growth and division of cells. The stages of the cell cycle include G<sub>0</sub> (Gap 0; rest phase), G<sub>1</sub> (Gap 1), S phase (DNA synthesis), G<sub>2</sub> (Gap 2) and M phase (mitosis).

The term "cell growth" as used herein refers to an increase in the size of a population of cells.

The term "cell division" as used herein refers to mitosis, i.e., the process of cell reproduction.

The term "proliferation" as used herein means growth and division of cells. "Actively proliferating" means cells that are actively growing and dividing.

The term "inhibiting cellular proliferation" as used herein refers to slowing and/or preventing the growth and division of cells. Cells may further be specified as being arrested in a particular cell cycle stage: G<sub>1</sub> (Gap 1), S phase (DNA synthesis), G<sub>2</sub> (Gap 2) or M phase (mitosis).

The term "preferentially inhibiting cellular proliferation" as used herein refers to slowing and/or preventing the growth and division of cells as compared to normal cells.

The term "metastasis" refers to the transfer of disease (e.g., cancer) from one organ and/or tissue to another not directly connected with it. As used herein, metastasis refers to neoplastic cell

growth in an unregulated fashion and spread to distal tissues and organs of the body.

The term "inhibiting metastasis" refers to slowing and/or preventing metastasis or the spread of neoplastic cells to a site remote from the primary growth area.

The term "invasion" as used herein refers to the spread of cancerous cells to surrounding  
5 tissues.

The term "inhibiting invasion" refers to slowing and/or preventing the spread of cancerous cells to surrounding tissues.

The term "apoptosis" as used herein refers to programmed cell death as signaled by the nuclei in normally functioning human and animal cells when age or state of cell health and  
10 condition dictates. "Apoptosis" is an active process requiring metabolic activity by the dying cell, often characterized by cleavage of the DNA into fragments that give a so called laddering pattern on gels. Cells that die by apoptosis do not usually elicit the inflammatory responses that are associated with necrosis, though the reasons are not clear. Cancerous cells, however, are unable to experience, or have a reduction in, the normal cell transduction or apoptosis-driven natural cell  
15 death process. Morphologically, apoptosis is characterized by loss of contact with neighboring cells, concentration of cytoplasm, endonuclease activity-associated chromatin condensation and pyknosis, and segmentation of the nucleus, among others.

The term "necrosis" as used herein refers to the sum of the morphological changes indicative of cell death and caused by the progressive degradative action of enzymes, it may affect  
20 groups of cells or part of a structure or an organ. Morphologically, necrosis is characterized by marked swelling of mitochondria, swelling of cytoplasm and nuclear alteration, followed by cell destruction and autolysis. It occurs passively or incidentally.

The term "inducing apoptosis" refers to increasing the number of cells that undergo apoptosis, or the rate by which cells undergo apoptosis, in a given cell population. Preferably the  
25 increase is at least 1.25, 1.5, 2, 5, 10, 50, 100, 500 or 1000 fold increase as compared to normal, untreated or negative control cells.

The term "inhibiting apoptosis" refers to any decrease in the number of cells which undergo apoptosis relative to an untreated control. Preferably, the decrease is at least 1.25, 1.5, 2,  
5, 10, 50, 100, 500 or 1000 fold decrease as compared to normal, untreated or negative control  
30 cells.

An "effective amount" of a composition disclosed herein or an agonist thereof, in reference to "inhibiting the cellular proliferation" of a neoplastic cell, is an amount capable of inhibiting, to some extent, the growth of target cells. The term further includes an amount capable of invoking a growth inhibitory, cytostatic and/or cytotoxic effect and/or apoptosis and/or necrosis of the target  
35 cells. An "effective amount" of a polypeptide of the present invention or an agonist thereof for purposes of inhibiting neoplastic cell growth may be determined empirically and in a routine manner using methods well known in the art.

A "therapeutically effective amount", in reference to the treatment of neoplastic disease or neoplastic cells, refers to an amount capable of invoking one or more of the following effects:

- (1) inhibition, to some extent, of tumor growth, including, (i) slowing down and (ii) complete growth arrest; (2) reduction in the number of tumor cells; (3) maintaining tumor size; (4) reduction in tumor size; (5) inhibition, including (i) reduction, (ii) slowing down or (iii) complete prevention, of tumor cell infiltration into peripheral organs; (6) inhibition, including (i) reduction, (ii) slowing down or (iii) complete prevention, of metastasis; (7) enhancement of anti-tumor immune response, which may result in (i) maintaining tumor size, (ii) reducing tumor size, (iii) slowing the growth of a tumor, (iv) reducing, slowing or preventing invasion or (v) reducing, slowing or preventing metastasis; and/or (8) relief, to some extent, of one or more symptoms associated with the disorder.
- A "therapeutically effective amount" of a polypeptide of the present invention or an agonist thereof for purposes of treatment of tumor may be determined empirically and in a routine manner.

A "growth inhibitory amount" of a Polypeptide of the present invention or an agonist thereof is an amount capable of inhibiting the growth of a cell, especially a malignant tumor cell, e.g., cancer cell, either *in vitro* or *in vivo*. A "growth inhibitory amount" of a polypeptide of the present invention or an agonist thereof for purposes of inhibiting neoplastic cell growth may be determined empirically and in a routine manner using methods well known in the art.

A "cytotoxic amount" of a polypeptide of the present invention or an agonist thereof is an amount capable of causing the destruction of a cell, especially tumor, e.g., cancer cell, either *in vitro* or *in vivo*. A "cytotoxic amount" of a polypeptide of the present invention or an agonist thereof for purposes of inhibiting neoplastic cell growth may be determined empirically and in a routine manner using methods well known in the art.

The terms "killing" or "inducing cytotoxicity" as used herein refer to inducing cell death by either apoptosis and/or necrosis, whereby embodiments of the invention include only apoptosis, only necrosis and both apoptosis and necrosis.

The term "cytotoxic agent" as used herein refers to a substance that inhibits or prevents the function of cells, for example by inhibiting progression of the cell cycle, and/or causes cell death. The term is intended to include radioactive isotopes, chemotherapeutic agents, and toxins such as enzymatically active toxins of bacterial, fungal, plant or animal origin, or fragments thereof.

The term "preventing" as used herein refers to administering a compound prior to the onset of clinical symptoms of a disease or condition so as to prevent a physical manifestation of the disease or condition. Alternatively, the term "preventing" can also be used to signify the reduction, or severity, of clinical symptoms associated with a disease or condition.

"Suppression" involves administration of drug prior to the clinical appearance of disease.

The term "treating" as used herein refers to administering a compound after the onset of clinical symptoms.

In human and veterinary medicine, we use the term "prophylaxis" as distinct from

"treatment" to encompass "preventing" and "suppressing". Herein, "protection" includes "prophylaxis". Protection need not be absolute to be useful.

The term "in need of treatment" as used herein refers to a judgment made by a caregiver (e.g. physician, nurse, nurse practitioner, etc in the case of humans; veterinarian in the case of animals, including non-human mammals) that an individual or animal requires or will benefit from treatment. This judgment is made based on a variety of factors that are in the realm of a caregiver's expertise, but that include the knowledge that the individual or animal is ill, or will be ill, as the result of a condition that is treatable by the compounds of the invention.

The term "perceives a need for treatment" refers to a sub-clinical determination that an individual desires treatment. The term "perceives a need for treatment" in other embodiments can refer to the decision that an owner of an animal makes for treatment of the animal.

The term "individual" or "patient" as used herein refers to any animal, including mammals, preferably mice, rats, other rodents, rabbits, dogs, cats, swine, cattle, sheep, horses, or primates, and most preferably humans. The term may specify male or female or both, or exclude male or female.

As used herein, the term "non-human animal" refers to any non-human animal, including insects, birds, rodents and more usually mammals. Preferred non-human animals include: primates; farm animals such as swine, goats, sheep, donkeys, cattle, horses, chickens, rabbits; and rodents, preferably rats or mice. As used herein, the term "animal" is used to refer to any species in the animal kingdom, preferably vertebrates, including birds and fish, and more preferable a mammal. Both the terms "animal" and "mammal" expressly embrace human subjects unless preceded with the term "non-human".

As used herein, the terms "physiologically acceptable," "pharmaceutically acceptable," and "pharmaceutical" are interchangeable.

## **25 Identity Between Nucleic Acids Or Polypeptides**

The terms "percentage of sequence identity" and "percentage homology" are used interchangeably herein to refer to comparisons among polynucleotides and polypeptides, and are determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide or polypeptide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. The percentage is calculated by determining the number of positions at which the identical nucleic acid base or amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison and multiplying the result by 100 to yield the percentage of sequence identity. Identity is evaluated using any of the variety of sequence comparison algorithms and programs known in the art. Such algorithms and programs include, but are by no means limited to, TBLASTN, BLASTP, FASTA,

TFASTA, CLUSTALW, FASTDB [Pearson and Lipman, (1988), Proc. Natl. Acad. Sci. USA 85(8):2444-2448; Altschul *et al.*, (1990), J. Mol. Biol. 215(3):403-410; Thompson *et al.* (1994), Nucleic Acids Res. 22(2):4673-4680; Higgins *et al.*, (1996), Meth. Enzymol. 266:383-402; Altschul *et al.*, (1993), Nature Genetics 3:266-272; Brutlag *et al.* (1990) Comp. App. Biosci. 6:237-24], the disclosures of which are incorporated by reference in their entireties.

In a particularly preferred embodiment, protein and nucleic acid sequence identities are evaluated using the Basic Local Alignment Search Tool ("BLAST") which is well known in the art [e.g., Karlin and Altschul, (1990), Proc. Natl. Acad. Sci. USA 87:2267-2268; Altschul *et al.*, (1997), Nuc. Acids Res. 25:3389-3402] the disclosures of which are incorporated by reference in their entireties. In particular, five specific BLAST programs are used to perform the following task:

- (1) LASTP and BLAST3 compare an amino acid query sequence against a protein sequence database;
- (2) BLASTN compares a nucleotide query sequence against a nucleotide sequence database;
- (3) LASTX compares the six-frame conceptual translation products of a query nucleotide sequence (both strands) against a protein sequence database;
- (4) BLASTN compares a query protein sequence against a nucleotide sequence database translated in all six reading frames (both strands); and
- (5) BLASTX compares the six-frame translations of a nucleotide query sequence against the six-frame translations of a nucleotide sequence database.

The BLAST programs identify homologous sequences by identifying similar segments, which are referred to herein as "high-scoring segment pairs," between a query amino or nucleic acid sequence and a test sequence which is preferably obtained from a protein or nucleic acid sequence database. High-scoring segment pairs are preferably identified (i.e., aligned) by means of a scoring matrix, many of which are known in the art. Preferably, the scoring matrix used is the BLOSUM62 matrix [Gonnet *et al.*, (1992), Science 256:1443-1445; Henikoff and Henikoff, (1993), Proteins 17:49-61, the disclosures of which are incorporated by reference in their entireties]. Less preferably, the PAM or PAM250 matrices may also be used [see, e.g., Schwartz and Dayhoff, (1978), eds., Matrices for Detecting Distance Relationships: Atlas of Protein Sequence and Structure, Washington: National Biomedical Research Foundation, the disclosure of which is incorporated by reference in its entirety]. The BLAST programs evaluate the statistical significance of all high-scoring segment pairs identified, and preferably selects those segments which satisfy a user-specified threshold of significance, such as a user-specified percent homology. Preferably, the statistical significance of a high-scoring segment pair is evaluated using the statistical significance formula of Karlin (see, e.g., Karlin and Altschul, 1990), the disclosure of which is incorporated by reference in its entirety. The BLAST programs may be used with the

default parameters or with modified parameters provided by the user.

Another preferred method for determining the best overall match between a query nucleotide sequence (a sequence of the present invention) and a subject sequence, also referred to as a global sequence alignment, can be determined using the FASTDB computer program based on the algorithm of Brutlag *et al.* (1990), the disclosure of which is incorporated by reference in its entirety. In a sequence alignment the query and subject sequences are both DNA sequences. An RNA sequence can be compared by first converting U's to T's. The result of said global sequence alignment is in percent identity. Preferred parameters used in a FASTDB alignment of DNA sequences to calculate percent identity are: Matrix = Unitary, k-tuple = 4, Mismatch Penalty = 1, Joining Penalty = 30, Randomization Group Length = 0, Cutoff Score = 1, Gap Penalty = 5, Gap Size Penalty = 0.05, Window Size = 500 or the length of the subject nucleotide sequence, whichever is shorter. If the subject sequence is shorter than the query sequence because of 5' or 3' deletions, not because of internal deletions, a manual correction must be made to the results. This is because the FASTDB program does not account for 5' and 3' truncations of the subject sequence when calculating percent identity. For subject sequences truncated at the 5' or 3' ends, relative to the query sequence, the percent identity is corrected by calculating the number of bases of the query sequence that are 5' and 3' of the subject sequence, which are not matched/aligned, as a percent of the total bases of the query sequence. Whether a nucleotide is matched/aligned is determined by results of the FASTDB sequence alignment. This percentage is then subtracted from the percent identity, calculated by the above FASTDB program using 10, the specified parameters, to arrive at a final percent identity score. This corrected score is what is used for the purposes of the present invention. Only nucleotides outside the 5' and 3' nucleotides of the subject sequence, as displayed by the FASTDB alignment, which are not matched/aligned with the query sequence, are calculated for the purposes of manually adjusting the percent identity score. For example, a 90 nucleotide subject sequence is aligned to a 100 nucleotide query sequence to determine percent identity. The deletions occur at the 5' end of the subject sequence and therefore, the FASTDB alignment does not show a matched/alignment of the first 10 nucleotides at 5' end. The 10 unpaired nucleotides represent 10% of the sequence (number of nucleotides at the 5' and 3' ends not matched/total number of nucleotides in the query sequence) so 10% is subtracted from the percent identity score calculated by the FASTDB program. If the remaining 90 nucleotides were perfectly matched the final percent identity would be 90%. In another example, a 90 nucleotide subject sequence is compared with a 100 nucleotide query sequence. This time the deletions are internal deletions so that there are no nucleotides on the 5' or 3' of the subject sequence which are not matched/aligned with the query. In this case the percent identity calculated by FASTDB is not manually corrected. Once again, only nucleotides 5' and 3' of the subject sequence which are not matched/aligned with the query sequence are manually corrected. No other manual corrections are made for the purposes of the present invention.

Another preferred method for determining the best overall match between a query amino acid sequence (a sequence of the present invention) and a subject sequence, also referred to as a global sequence alignment, can be determined using the FASTDB computer program based on the algorithm of Brutlag *et al.* (1990). In a sequence alignment the query and subject sequences are both amino acid sequences. The result of said global sequence alignment is in percent identity. Preferred parameters used in a FASTDB amino acid alignment are: Matrix = PAM 0, k-tuple = 2, Mismatch Penalty = 1, Joining Penalty = 20, Randomization Group Length = 0, Cutoff Score = 1, Window Size = sequence length, Gap Penalty = 5, Gap Size Penalty = 0.05, Window Size = 500 or the length of the subject amino acid sequence, whichever is shorter. If the subject sequence is shorter than the query sequence due to N-or C-terminal deletions, not because of internal deletions, the results, in percent identity, must be manually corrected. This is because the FASTDB program does not account for N- and C-terminal truncations of the subject sequence when calculating global percent identity. For subject sequences truncated at the N- and C-termini, relative to the query sequence, the percent identity is corrected by calculating the number of residues of the query sequence that are N- and C- terminal of the subject sequence, which are not matched/aligned with a corresponding subject residue, as a percent of the total bases of the query sequence. Whether a residue is matched/aligned is determined by results of the FASTDB sequence alignment. This percentage is then subtracted from the percent identity, calculated by the above FASTDB program using the specified parameters, to arrive at a final percent identity score. This final percent identity score is what is used for the purposes of the present invention. Only residues to the N- and C-termini of the subject sequence, which are not matched/aligned with the query sequence, are considered for the purposes of manually adjusting the percent identity score. That is, only query amino acid residues outside the farthest N- and C-terminal residues of the subject sequence. For example, a 90 amino acid residue subject sequence is aligned with a 100-residue query sequence to determine percent identity. The deletion occurs at the N-terminus of the subject sequence and therefore, the FASTDB alignment does not match/align with the first residues at the N-terminus. The 10 unpaired residues represent 10% of the sequence (number of residues at the N- and C-termini not matched/total number of residues in the query sequence) so 10% is subtracted from the percent identity score calculated by the FASTDB program. If the remaining 90 residues were perfectly matched the final percent identity would be 90%. In another example, a 90-residue subject sequence is compared with a 100-residue query sequence. This time the deletions are internal so there are no residues at the N- or C-termini of the subject sequence, which are not matched/aligned with the query. In this case the percent identity calculated by FASTDB is not manually corrected. Once again, only residue positions outside the N- and C-terminal ends of the subject sequence, as displayed in the FASTDB alignment, which are not matched/aligned with the query sequence are manually corrected. No other manual corrections are made for the purposes of the present invention.

The term "percentage of sequence similarity" refers to comparisons between polypeptide sequences and is determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polypeptide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. The percentage is calculated by determining the number of positions at which an identical or equivalent amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison and multiplying the result by 100 to yield the percentage of sequence similarity. Similarity is evaluated using any of the variety of sequence comparison algorithms and programs known in the art, including those described above in this section. Equivalent amino acid residues are defined herein in the "Mutated polypeptides" section.

#### **POLYNUCLEOTIDES OF THE INVENTION**

The present invention concerns GENSET genomic and cDNA sequences. The present invention encompasses GENSET genes, polynucleotides comprising GENSET genomic and cDNA sequences, as well as fragments and variants thereof. These polynucleotides may be purified, isolated, or recombinant.

Also encompassed by the present invention are allelic variants, orthologs, splice variants, and/or species homologues of the GENSET genes. Procedures known in the art can be used to obtain full-length genes and cDNAs, allelic variants, splice variants, full-length coding portions, orthologs, and/or species homologues of genes and cDNAs corresponding to a nucleotide sequence selected from the group consisting of sequences of odd SEQ ID NOs: 1-111 and sequences of clone inserts of the deposited clone pool, using information from the sequences disclosed herein or the clone pool deposited with the ATCC. For example, allelic variants, orthologs and/or species homologues may be isolated and identified by making suitable probes or primers from the sequences provided herein and screening a suitable nucleic acid source for allelic variants and/or the desired homologue using any technique known to those skilled in the art including those described into the section entitled "To find similar sequences".

In a specific embodiment, the polynucleotides of the invention are at least 15, 30, 50, 100, 125, 500, or 1000 continuous nucleotides. In another embodiment, the polynucleotides are less than or equal to 300kb, 200kb, 100kb, 50kb, 10kb, 7.5kb, 5kb, 2.5kb, 2kb, 1.5kb, or 1kb in length. In a further embodiment, polynucleotides of the invention comprise a portion of the coding sequences, as disclosed herein, but do not comprise all or a portion of any intron. In another embodiment, the polynucleotides comprising coding sequences do not contain coding sequences of a genomic flanking gene (i.e., 5' or 3' to the gene of interest in the genome). In other embodiments, the polynucleotides of the invention do not contain the coding sequence of more than 1000, 500, 250, 100, 75, 50, 25, 20, 15, 10, 5, 4, 3, 2, or 1 naturally occurring genomic

flanking gene(s).

### Deposited clone pool of the invention

Expression of GENSET genes has been shown to lead to the production of at least one mRNA species per GENSET gene, which cDNA sequence is set forth in the appended Sequence Listing as odd SEQ ID NOs: 1-111. The cDNAs corresponding to these GENSET mRNA species were cloned either in the vector pBluescriptII SK<sup>-</sup> (Stratagene) or in a vector called pPT. Cells containing the cloned cDNAs of the present invention are maintained in permanent deposit by the inventors at Genset, S.A., 24 Rue Royale, 75008 Paris, France. Table I provides Genset's internal designation number assigned to each SEQ ID NO., and indicates whether the sequence is a nucleic acid sequence (DNA) or a protein (PRT) sequence. Each cDNA can be removed from the Bluescript vector in which it was inserted by performing a NotI Pst I double digestion, or from the pPT vector by performing a MunI HindIII double digestion, to produce the appropriate fragment for each clone, provided the cDNA sequence does not contain any of the corresponding restriction sites within its sequence. Alternatively, other restriction enzymes of the multicloning site of the vector may be used to recover the desired insert as indicated by the manufacturer.

Pools of cells containing GENSET genes as described in the Sequence Listing, from which the cells containing a particular polynucleotide is obtainable, were or will be also deposited with the American Tissue Culture Collection (ATCC), 10801 University Boulevard, Manassas, VA 20110-2209, United States. Each cDNA clone has been transfected into separate bacterial cells (*E. coli*) for these composite deposits.

Bacterial cells containing a particular clone can be obtained from the composite deposit as follows:

An oligonucleotide probe or probes should be designed to the sequence that is known for that particular clone. This sequence can be derived from the sequences provided herein, or from a combination of those sequences. The design of the oligonucleotide probe should preferably follow these parameters:

- (a) it should be designed to an area of the sequence which has the fewest ambiguous bases ("N's"), if any;
- (b) preferably, the probe is designed to have a T<sub>m</sub> of approximately 80 degrees Celsius (assuming 2 degrees for each A or T and 4 degrees for each G or C). However, probes having melting temperatures between 40 degrees Celsius and 80 degrees Celsius may also be used provided that specificity is not lost.

The oligonucleotide should preferably be labeled with gamma[<sup>32</sup>P]ATP (specific activity 6000 Ci/mmol) and T4 polynucleotide kinase using commonly employed techniques for labeling oligonucleotides. Other labeling techniques can also be used. Unincorporated label should preferably be removed by gel filtration chromatography or other established methods. The amount of radioactivity incorporated into the probe should be quantified by measurement in a scintillation

counter. Preferably, specific activity of the resulting probe should be approximately  $4 \times 10^6$  dpm/pmole.

The bacterial culture containing the pool of full-length clones should preferably be thawed and 100 ul of the stock used to inoculate a sterile culture flask containing 25 ml of sterile L-broth containing ampicillin at 100 ug/ml. The culture should preferably be grown to saturation at 37 degrees Celsius, and the saturated culture should preferably be diluted in fresh L-broth. Aliquots of these dilutions should preferably be plated to determine the dilution and volume which will yield approximately 5000 distinct and well-separated colonies on solid bacteriological media containing L-broth containing ampicillin at 100 ug/ml and agar at 1.5% in a 150 mm petri dish when grown overnight at 37 degrees Celsius. Other known methods of obtaining distinct, well-separated colonies can also be employed.

Standard colony hybridization procedures should then be used to transfer the colonies to nitrocellulose filters and lyse, denature and bake them.

The filter is then preferably incubated at 65 degrees Celsius for 1 hour with gentle agitation in 6X SSC (20X stock is 175.3 g NaCl/liter, 88.2 g Na citrate/liter, adjusted to pH 7.0 with NaOH) containing 0.5% SDS, 100 pg/ml of yeast RNA, and 10 mM EDTA (approximately 10 ml per 150 mm filter). Preferably, the probe is then added to the hybridization mix at a concentration greater than or equal to  $1 \times 10^6$  dpm/ml. The filter is then preferably incubated at 65 degrees Celsius with gentle agitation overnight. The filter is then preferably washed in 500 ml of 2X SSC/0.1% SDS at room temperature with gentle shaking for 15 minutes. A third wash with 0.1X SSC/0.5% SDS at 65 degrees Celsius for 30 minutes to 1 hour is optional. The filter is then preferably dried and subjected to autoradiography for sufficient time to visualize the positives on the X-ray film. Other known hybridization methods can also be employed.

The positive colonies are picked, grown in culture, and plasmid DNA isolated using standard procedures. The clones can then be verified by restriction analysis, hybridization analysis, or DNA sequencing. The plasmid DNA obtained using these procedures may then be manipulated using standard cloning techniques familiar to those skilled in the art.

Alternatively, to recover cDNA inserts from the pool of bacteria, a PCR can be performed on plasmid DNA isolated using standard procedures and primers designed at both ends of the cDNA insertion, including primers designed in the multicloning site of the vector. If a specific cDNA of interest is to be recovered, primers may be designed in order to be specific for the 5' end and the 3' end of this cDNA using sequence information available from the appended sequence listing. The PCR product which corresponds to the cDNA of interest can then be manipulated using standard cloning techniques familiar to those skilled in the art.

Therefore, an object of the invention is an isolated, purified, or recombinant polynucleotide comprising a nucleotide sequence selected from the group consisting of human cDNA inserts of the deposited clone pool. Moreover, preferred polynucleotides of the invention include purified,

isolated, or recombinant GENSET cDNAs consisting of, consisting essentially of, or comprising a nucleotide sequence selected from the group consisting of human cDNA inserts of the deposited clone pool.

**cDNA sequences of the invention**

- 5 Another object of the invention is a purified, isolated, or recombinant polynucleotide comprising a nucleotide sequence selected from the group consisting of the polynucleotide sequences of the appended Sequence Listing, the sequences of human cDNA clone inserts of the deposited clone pool, complementary sequences thereto, and fragments thereof. Moreover, preferred polynucleotides of the invention include purified, isolated, or recombinant GENSET
- 10 cDNAs consisting of, consisting essentially of, or comprising a sequence selected from the group consisting of the polynucleotide sequences of the Sequence Listing and the sequences of clone inserts of the deposited clone pool.

- Structural parameters of each of the cDNAs of the present invention are presented in the appended Sequence Listing. Accordingly, the coding sequence (CDS) or open reading frame (ORF) of each
- 15 cDNA of the invention refers to the nucleotide sequence beginning with the first nucleotide of the start codon and ending with the last nucleotide of the stop codon. Similarly, the 5' untranslated region (or 5'UTR) of each cDNA of the invention refers to the nucleotide sequence starting at nucleotide 1 and ending at the nucleotide immediately 5' to the first nucleotide of the start codon. The 3' untranslated region (or 3'UTR) of each cDNA of the invention refers to the nucleotide
- 20 sequence starting at the nucleotide immediately 3' to the last nucleotide of the stop codon and ending at the last nucleotide of the cDNA.

Untranslated regions

- In addition, the invention concerns a purified, isolated, and recombinant nucleic acid comprising a nucleotide sequence selected from the group consisting of the 5'UTRs of the
- 25 polynucleotide sequences of the appended Sequence Listing, those of human cDNA clone inserts of the deposited clone pool, sequences complementary thereto, and allelic variants thereof. The invention also concerns a purified, isolated, and/or recombinant nucleic acid comprising a nucleotide sequence selected from the group consisting of the 3'UTRs of the polynucleotide sequences of the appended Sequence Listing, those of human cDNA clone inserts of the deposited
- 30 clone pool, sequences complementary thereto, and allelic variants thereof.

These polynucleotides may be used to detect the presence of GENSET mRNA species in a biological sample using either hybridization or RT-PCR techniques well known to those skilled in the art.

- In addition, these polynucleotides may be used as regulatory molecules able to affect the
- 35 processing and maturation of any polynucleotide including them (either a GENSET polynucleotide or an heterologous polynucleotide), preferably the localization, stability and/or translation of said polynucleotide including them [for a review on UTRs see Decker and Parker, (1995) Curr. Opin.

Cell. Biol. 7(3) :368-92, Derrigo *et al.*, (2000) Int. J. Mol. Med. 5(2) :111-23]. In particular, 3'UTRs may be used in order to control the stability of heterologous mRNAs in recombinant vectors using any methods known to those skilled in the art including Makrides (1999) Protein Expr Purif 1999 Nov;17(2):183-202), US Patents 5,925,564; 5,807,707 and 5,756,264, which  
5 disclosures are hereby incorporated by reference in their entireties.

#### Coding sequences

Another object of the invention is an isolated, purified or recombinant polynucleotide comprising the coding sequence of a sequence selected from the group consisting of the polynucleotide sequences of the appended Sequence Listing, those of human cDNA clone inserts  
10 of the deposited clone pool and variants thereof.

A further object of the invention is an isolated, purified, or recombinant polynucleotide encoding a polypeptide of the present invention.

It will be appreciated that should the extent of the coding sequence differ from that indicated in the appended sequence listing as a result of a sequencing error, reverse transcription or  
15 amplification error, mRNA splicing, post-translational modification of the encoded protein, enzymatic cleavage of the encoded protein, or other biological factors, one skilled in the art would be readily able to identify the extent of the coding sequences in the polynucleotide sequences of the Sequence Listing, those of the human cDNA inserts of the deposited clone pool, and allelic variants thereof. Accordingly, the scope of any claims herein relating to nucleic acids containing  
20 the coding sequence of one of the polynucleotide sequences of the Sequence Listing and those of the cDNA inserts of the deposited clone pool is not to be construed as excluding any readily identifiable variations from or equivalents to the coding sequences described in the appended sequence listing. Equivalents include any alterations in a nucleotide coding sequence that does not result in an amino acid change, or that results in a conservative amino acid substitution, as defined  
25 below, in the polypeptide encoded by the nucleotide sequence. Similarly, should the extent of the polypeptides differ from those indicated in the appended Sequence Listing as a result of any of the preceding factors, the scope of claims relating to polypeptides comprising the amino acid sequence of the polypeptide sequences of the appended Sequence Listing is not to be construed as excluding any readily identifiable variations from or equivalents to the sequences described in the appended  
30 sequence listing.

The above disclosed polynucleotides that contain the coding sequence of the GENSET genes may be expressed in a desired host cell or a desired host organism, when this polynucleotide is placed under the control of suitable expression signals. The expression signals may be either the expression signals contained in the regulatory regions in the GENSET genes of the invention or, in  
35 contrast, the signals may be exogenous regulatory nucleic sequences. Such a polynucleotide, when placed under the suitable expression signals, may also be inserted in a vector for its expression and/or amplification.

Further included in the present invention are polynucleotides encoding the polypeptides of the present invention that are fused in frame to the coding sequences for additional heterologous amino acid sequences. Also included in the present invention are nucleic acids encoding polypeptides of the present invention together with additional, non-coding sequences, including, but not limited to, non-coding 5' and 3' sequences, vector sequence, sequences used for purification, probing, or priming. For example, heterologous sequences include transcribed, untranslated sequences that may play a role in transcription and mRNA processing, such as ribosome binding and stability of mRNA. The heterologous sequences may alternatively comprise additional coding sequences that provide additional functionalities. Thus, a nucleotide sequence encoding a polypeptide may be fused to a tag sequence, such as a sequence encoding a peptide that facilitates purification or detection of the fused polypeptide. In certain preferred embodiments of this aspect of the invention, the tag amino acid sequence is a hexa-histidine peptide, such as the tag provided in a pQE vector (QIAGEN), or in any of a number of additional, commercially available vectors. For instance, hexa-histidine provides for the convenient purification of the fusion protein (see, Gentz *et al.*, 1989, Proc Natl Acad Sci U S A Feb; 86(3):821-4, the disclosure of which is incorporated by reference in its entirety). The "HA" tag is another peptide useful for purification which corresponds to an epitope derived from the influenza hemagglutinin protein (see, Wilson, *et al.*, 1984, Cell Jul; 37(3):767-78, the disclosure of which is incorporated by reference in its entirety). As discussed below, other such fusion proteins include a GENSET polypeptide fused to Fc at the N- or C- terminus.

#### **Regulatory sequences of the invention**

As mentioned, the genomic sequence of GENSET genes contain regulatory sequences in the non-coding 5'-flanking region and possibly in the non-coding 3'-flanking region that border the GENSET polypeptide coding regions containing the exons of these genes.

Polynucleotides derived from GENSET polynucleotide 5' and 3' regulatory regions are useful in order to detect the presence of at least a copy of a genomic nucleotide sequence of the GENSET gene or a fragment thereof in a test sample.

#### **Preferred regulatory sequences**

Polynucleotides carrying the regulatory elements located at the 5' end and at the 3' end of GENSET polypeptide coding regions may be advantageously used to control, e.g., the transcriptional and translational activity of a heterologous polynucleotide of interest.

Thus, the present invention also concerns a purified or isolated nucleic acid comprising a polynucleotide which is selected from the group consisting of the 5' and 3' GENSET polynucleotide regulatory regions, sequences complementary thereto, regulatory active fragments and variants thereof.

Another object of the invention consists of purified, isolated or recombinant nucleic acids comprising a polynucleotide that hybridizes, under the stringent hybridization conditions defined

herein, with a polynucleotide of the present invention.

Preferred fragments of 5' and 3' regulatory regions are any one integer between 20 and 20,000 nucleotides in length.

For the purpose of the invention, a nucleic acid or polynucleotide is "functional" as a "regulatory region" for expressing a recombinant polypeptide or a recombinant polynucleotide if said regulatory polynucleotide contains nucleotide sequences which contain transcriptional and translational regulatory information, and such sequences are "operably linked" to nucleotide sequences which encode the desired polypeptide or the desired polynucleotide. The regulatory polynucleotides of the invention may be prepared using methods known in the art.

The regulatory polynucleotides according to the invention may be part of a recombinant expression vector that may be used to express a coding sequence in a desired host cell or host organism.

Preferred 5'-regulatory polynucleotides of the invention include 5'-UTRs of GENSET cDNAs, or regulatory active fragments or variants thereof.

Preferred 3'-regulatory polynucleotide of the invention include 3'-UTRs of GENSET cDNAs, or regulatory active fragments or variants thereof.

A further object of the invention consists of a purified or isolated nucleic acid comprising:

- a) polynucleotide comprising a 5' regulatory nucleotide sequence selected from the group consisting of:
  - (i) a nucleotide sequence comprising a polynucleotide of a GENSET polynucleotide 5' regulatory region or a complementary sequence thereto;
  - (ii) a nucleotide sequence comprising a polynucleotide having at least 95% of nucleotide identity with the nucleotide sequence of a GENSET polynucleotide 5' regulatory region or a complementary sequence thereto;
  - (iii) a nucleotide sequence comprising a polynucleotide that hybridizes under stringent hybridization conditions with the nucleotide sequence of a GENSET polynucleotide 5' regulatory region or a complementary sequence thereto; and
  - (iv) a regulatory active fragment or variant of the polynucleotides in (i), (ii) and (iii);
- b) a nucleic acid molecule encoding a desired polypeptide or a nucleic acid molecule of interest, wherein said nucleic acid molecule is operably linked to the polynucleotide defined in (a); and
- c) optionally, a polynucleotide comprising a 3'- regulatory polynucleotide, preferably a 3'- regulatory polynucleotide of a GENSET gene.

In a specific embodiment, the nucleic acid defined above includes the 5'-UTR of a GENSET cDNA, or a regulatory active fragment or variant thereof.

The regulatory polynucleotide of the 3' regulatory region, or its regulatory active fragments or variants, is advantageously operably linked at the 3'-end of the nucleic acid molecule encoding the desired polypeptide or nucleic acid molecule of interest.

The desired polypeptide encoded by the above-described nucleic acid may be of various nature or origin, encompassing proteins of prokaryotic viral or eukaryotic origin. Among the polypeptides expressed under the control of a GENSET polynucleotide regulatory region include bacterial, fungal or viral antigens. Also encompassed are eukaryotic proteins such as intracellular proteins, such as "house keeping" proteins, membrane-bound proteins, such as mitochondrial membrane-bound proteins and cell surface receptors, and secreted proteins such as endogenous mediators such as cytokines. The desired polypeptide may be a heterologous polypeptide or a GENSET polypeptide, especially a protein with an amino acid sequence selected from the group consisting of the polypeptide sequences of the Sequence Listing, those encoded by the cDNA inserts of the deposited clone pool, fragments and variants thereof.

The desired nucleic acids encoded by the above-described polynucleotides, usually an RNA molecule, may be complementary to a desired coding polynucleotide, for example to a GENSET coding sequence, and thus useful as an antisense polynucleotide. Such a polynucleotide may be included in a recombinant expression vector in order to express the desired polypeptide or the desired nucleic acid in host cell or in a host organism. Suitable recombinant vectors that contain a polynucleotide such as described herein are disclosed elsewhere in the specification.

## **20 Polynucleotide variants**

The invention also relates to variants of the polynucleotides described herein and fragments thereof. "Variants" of polynucleotides, as the term is used herein, are polynucleotides that differ from a reference polynucleotide. Generally, differences are limited so that the nucleotide sequences of the reference and the variant are closely similar overall and, in many regions, identical. The present invention encompasses both allelic variants and degenerate variants.

### Allelic variant

A variant of a polynucleotide may be a naturally occurring variant such as a naturally occurring allelic variant, or it may be a variant that is not known to occur naturally. By an "allelic variant" is intended one of several alternate forms of a gene occupying a given locus on a chromosome of an organism [see Lewin, (1989), Proc. Natl. Acad. Sci. USA 86:9832-8935], the disclosure of which is incorporated by reference in its entirety. Diploid organisms may be homozygous or heterozygous for an allelic form. Non-naturally occurring variants of the polynucleotide may be made by art-known mutagenesis techniques, including those applied to polynucleotides, cells or organisms. See, for example, Table III, which provides sets of related cDNAs of the invention, e.g. sets of sequences representing allelic variants of a single gene.

### Degenerate variant

In addition to the isolated polynucleotides of the present invention, and fragments thereof, the invention further includes polynucleotides which comprise a sequence substantially different from those described above but which, due to the degeneracy of the genetic code, still encode a GENSET polypeptide of the present invention. These polynucleotide variants are referred to as  
5 “degenerate variants” throughout the instant application. That is, all possible polynucleotide sequences that encode the GENSET polypeptides of the present invention are contemplated. This includes the genetic code and species-specific codon preferences known in the art.

Nucleotide changes present in a variant polynucleotide may be silent, which means that they do not alter the amino acids encoded by the polynucleotide. However, nucleotide changes  
10 may also result in amino acid substitutions, additions, deletions, fusions and truncations in the polypeptide encoded by the reference sequence. The substitutions, deletions or additions may involve one or more nucleotides. The variants may be altered in coding or non-coding regions or both. Alterations in the coding regions may produce conservative or non-conservative amino acid substitutions, deletions or additions. In the context of the present invention, preferred  
15 embodiments are those in which the polynucleotide variants encode polypeptides which retain substantially the same biological properties or activities as the GENSET protein. More preferred polynucleotide variants are those containing conservative substitutions.

#### Similar polynucleotides

Other embodiments of the present invention provide a purified, isolated or recombinant  
20 polynucleotide which is at least 80%, 85%, 90%, 95%, 96%, 97%, 98% or 99% identical to a polynucleotide of the present invention. The above polynucleotides are included regardless of whether they encode a polypeptide having a GENSET biological activity. This is because even where a particular nucleic acid molecule does not encode a polypeptide having activity, one of skill in the art would still know how to use the nucleic acid molecule, for instance, as a hybridization  
25 probe or primer. Uses of the nucleic acid molecules of the present invention that do not encode a polypeptide having GENSET activity include, inter alia, isolating a GENSET gene or allelic variants thereof from a DNA library, and detecting GENSET mRNA expression in biological samples suspected of containing GENSET mRNA or DNA, e.g., by Northern Blot or PCR analysis.

30 The present invention is further directed to polynucleotides having sequences at least 50%. 60%, 70%, 80%, 90%, 95%, 96%, 97%, 98% or 99% identity to a polynucleotide, where said polynucleotides do, in fact, encode a polypeptide having a GENSET biological activity. Of course, due to the degeneracy of the genetic code, one of ordinary skill in the art will immediately recognize that a large number of the polynucleotides at least 50%. 60%, 70%, 80%, 90%, 95%,  
35 96%, 97%, 98%, or 99% identical to a polynucleotide selected from the group consisting of polynucleotide sequences of the Sequence Listing and those of human cDNA clone inserts of the deposited clone pool will encode a polypeptide having biological activity. By a polynucleotide

having a nucleotide sequence at least, for example, 95% "identical" to a reference nucleotide sequence of the present invention, it is intended that the nucleotide sequence of the polynucleotide is identical to the reference sequence except that the polynucleotide sequence may include up to five point mutations per each 100 nucleotides of the reference nucleotide sequence encoding the

5 GENSET polypeptide. In other words, to obtain a polynucleotide having a nucleotide sequence at least 95% identical to a reference nucleotide sequence, up to 5% of the nucleotides in the reference sequence may be deleted, inserted, or substituted with another nucleotide. The query sequence may be any polynucleotide of the present invention.

#### Hybridizing Polynucleotides

10 In another aspect, the invention provides an isolated or purified nucleic acid molecule comprising a polynucleotide which hybridizes under stringent hybridization conditions to any polynucleotide of the present. Such hybridizing polynucleotides may be of at least any one integer between 10 and 10,000 nucleotides in length.

Of course, a polynucleotide which hybridizes only to polyA+ sequences (such as any 3' terminal polyA+ tract of a cDNA shown in the sequence listing), or to a 5' complementary stretch of T (or U) residues, would not be included in the definition of "polynucleotide," since such a polynucleotide would hybridize to any nucleic acid molecule containing a poly(A) stretch or the complement thereof (e.g., practically any double-stranded cDNA clone generated using oligo dT as a primer).

#### 20 **Complementary polynucleotides**

The invention further provides isolated nucleic acid molecules having a nucleotide sequence fully complementary to any polynucleotide of the invention.

#### **Polynucleotide fragments**

The present invention is further directed to portions or fragments of the polynucleotides of

25 the present invention. Uses for the polynucleotide fragments of the present invention include probes, primers, molecular weight markers and for expressing the polypeptide fragments of the present invention. Fragments include portions of polynucleotides selected from the group consisting of a) polynucleotide sequences of the Sequence Listing, b) genomic GENSET sequences, c) polynucleotides encoding a polypeptide of the present invention, d) sequences of

30 human cDNA clone inserts of the deposited clone pool, and e) polynucleotides encoding the polypeptides encoded by the human cDNA clone inserts of the deposited clone pool. Particularly included in the present invention is a purified or isolated polynucleotide comprising at least 8 consecutive bases of a polynucleotide of the present invention. In one aspect of this embodiment, the polynucleotide comprises at least 10, 12, 15, 18, 20, 25, 28, 30, 35, 40, 50, 75, 100, 150, 200,

35 300, 400, 500, 800, 1000, 1500, or 2000 consecutive nucleotides of a polynucleotide of the present invention.

In addition to the above preferred polynucleotide sizes, further preferred sub-genuses of

polynucleotides comprise at least X nucleotides, wherein "X" is defined as any integer between 8 and the integer representing the 3' most nucleotide position as set forth in the sequence listing or elsewhere herein. Further included as preferred polynucleotides of the present invention are polynucleotide fragments at least X nucleotides in length, as described above, that are further  
5 specified in terms of their 5' and 3' position. The 5' and 3' positions are represented by the position numbers set forth in the appended sequence listing wherein the 5' most nucleotide is 1 and the 3' most nucleotide is the last nucleotide for a particular SEQ ID No. For allelic, degenerate and other variants, position 1 is defined as the 5' most nucleotide of the ORF, i.e., the nucleotide "A" of the start codon with the remaining nucleotides numbered consecutively. Therefore, every  
10 combination of a 5' and 3' nucleotide position that a polynucleotide fragment of the present invention, at least 8 contiguous nucleotides in length, could occupy on a polynucleotide of the invention is included in the invention as an individual species. The polynucleotide fragments specified by 5' and 3' positions can be immediately envisaged and are therefore not individually listed solely for the purpose of not unnecessarily lengthening the specification.

15 It is noted that the above species of polynucleotide fragments of the present invention may alternatively be described by the formula "a to b"; where "a" equals the 5' most nucleotide position and "b" equals the 3' most nucleotide position of the polynucleotide; and further where "a" equals an integer between 1 and the number of nucleotides of the polynucleotide sequence of the present invention minus 8, and where "b" equals an integer between 9 and the number of nucleotides of the  
20 polynucleotide sequence of the present invention; and where "a" is an integer smaller than "b" by at least 8.

The present invention also provides for the exclusion of any species of polynucleotide fragments of the present invention specified by 5' and 3' positions or sub-genuses of polynucleotides specified by size in nucleotides as described above. Any number of fragments  
25 specified by 5' and 3' positions or by size in nucleotides, as described above, may be excluded. Preferred excluded fragments include those having substantial homology to repeated sequences including Alu, L1, THE and MER repeats, SSTR sequences or satellite, micro-satellite, and telomeric repeats.

Other preferred fragments of the invention are polynucleotides comprising polynucleotide  
30 sequences encoding domains of polypeptides. Such fragments may be used to obtain other polynucleotides encoding polypeptides having similar domains using hybridization or RT-PCR techniques. Alternatively, these fragments may be used to express a polypeptide domain which may have a specific biological property.

Another object of the invention is an isolated, purified or recombinant polynucleotide  
35 encoding a polypeptide consisting of, consisting essentially of, or comprising a contiguous span of at least (any integer between 5 and 1,000 consecutive amino acids in length more preferably at least) 5, 6, 8, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 150 or 200 consecutive amino.

The present invention further encompasses any combination of the polynucleotide fragments listed in this section.

### **Oligonucleotide primers and probes**

The present invention also encompasses fragments of GENSET polynucleotides for use as  
5 primers and probes. Polynucleotides derived from the GENSET genomic and cDNA sequences are useful in order to detect the presence of at least a copy of a GENSET polynucleotide or fragment, complement, or variant thereof in a test sample.

### Structural definition

Any polynucleotide of the invention may be used as a primer or probe. Particularly  
10 preferred probes and primers of the invention include isolated, purified, or recombinant polynucleotides comprising a contiguous span of at least 12, 15, 18, 20, 25, 30, 35, 40, 50, 60, 70, 80, 90, 100, 150, 200, 500, or 1000 nucleotides of a polynucleotide of the present invention.

For amplification purposes, pairs of primers with approximately the same  $T_m$  are preferable. Primers may be designed using methods known in the art. Amplification techniques  
15 that can be used in the context of the present invention include, but are not limited to, the ligase chain reaction (LCR) described in EP-A- 320 308, WO 9320227 and EP-A-439 182, the polymerase chain reaction (PCR, RT-PCR) and techniques such as the nucleic acid sequence based amplification (NASBA) described in Guatelli *et al.*, (1990) Proc. Natl. Acad. Sci. USA 35:273-286 and in Compton (1991) Nature 350(6313):91-92, Q-beta amplification as described in European  
20 Patent Application No 4544610, strand displacement amplification as described in Walker, *et al.* (1996), Clin. Chem. 42:9-13 and EP A 684 315 and, target mediated amplification as described in PCT Publication WO 9322461, the disclosures of which are incorporated by reference in their entireties.

The probes of the present invention are useful for a number of purposes. They can notably  
25 be used in Southern hybridization to genomic DNA. The probes can also be used to detect PCR amplification products. They may also be used to detect mismatches in the GENSET gene or mRNA using other techniques. They may also be used to in situ hybridization.

Any of the polynucleotides, primers and probes of the present invention can be conveniently immobilized on a solid support. The solid support is not critical and can be selected by one skilled  
30 in the art. Thus, latex particles, microparticles, magnetic beads, non-magnetic beads (including polystyrene beads), membranes (including nitrocellulose strips), plastic tubes, walls of microtiter wells, glass or silicon chips, sheep (or other suitable animal's) red blood cells and duracytes are all suitable examples. Suitable methods for immobilizing nucleic acids on solid phases include ionic, hydrophobic, covalent interactions and the like. A solid support, as used herein, refers to any  
35 material which is insoluble, or can be made insoluble by a subsequent reaction. The solid support can be chosen for its intrinsic ability to attract and immobilize the capture reagent. Alternatively, the solid phase can retain an additional receptor which has the ability to attract and immobilize the

capture reagent. The additional receptor can include a charged substance that is oppositely charged with respect to the capture reagent itself or to a charged substance conjugated to the capture reagent. As yet another alternative, the receptor molecule can be any specific binding member which is immobilized upon (attached to) the solid support and which has the ability to immobilize the capture reagent through a specific binding reaction. The receptor molecule enables the indirect binding of the capture reagent to a solid support material before the performance of the assay or during the performance of the assay. The solid phase thus can be a plastic, derivatized plastic, magnetic or non-magnetic metal, glass or silicon surface of a test tube, microtiter well, sheet, bead, microparticle, chip, sheep (or other suitable animal's) red blood cells, duracytes® and other configurations known to those of ordinary skill in the art. The polynucleotides of the invention can be attached to or immobilized on a solid support individually or in groups of at least 2, 5, 8, 10, 12, 15, 20, or 25 distinct polynucleotides of the invention to a single solid support. In addition, polynucleotides other than those of the invention may be attached to the same solid support as one or more polynucleotides of the invention.

15 Oligonucleotide array

A substrate comprising a plurality of oligonucleotide primers or probes of the invention may be used either for detecting or amplifying targeted sequences in GENSET genes, may be used for detecting mutations in the coding or in the non-coding sequences of GENSET genes, and may also be used to determine GENSET gene expression in different contexts such as in different tissues, at different stages of a process (embryo development, disease treatment), and in patients versus healthy individuals as described elsewhere in the application.

As used herein, the term "array" means a one dimensional, two dimensional, or multidimensional arrangement of nucleic acids of sufficient length to permit specific detection of gene expression. For example, the array may contain a plurality of nucleic acids derived from genes whose expression levels are to be assessed. The array may include a GENSET genomic DNA, a GENSET cDNA, sequences complementary thereto or fragments thereof. Preferably, the fragments are at least 12, 15, 18, 20, 25, 30, 35, 40 or 50 nucleotides in length. More preferably, the fragments are at least 100 nucleotides in length. Even more preferably, the fragments are more than 100 nucleotides in length. In some embodiments the fragments may be more than 500 nucleotides in length.

Any polynucleotide provided herein may be attached in overlapping areas or at random locations on the solid support. Alternatively the polynucleotides of the invention may be attached in an ordered array wherein each polynucleotide is attached to a distinct region of the solid support which does not overlap with the attachment site of any other polynucleotide. Preferably, such an ordered array of polynucleotides is designed to be "addressable" where the distinct locations are recorded and can be accessed as part of an assay procedure. Addressable polynucleotide arrays typically comprise a plurality of different oligonucleotide probes that are coupled to a surface of a

substrate in different known locations. The knowledge of the precise location of each polynucleotides location makes these "addressable" arrays particularly useful in hybridization assays. Any addressable array technology known in the art can be employed with the polynucleotides of the invention. One particular embodiment of these polynucleotide arrays is known as the Genechips™, and has been generally described in US Patent No. 5,143,854; PCT publications WO 90/15070 and 92/10092, which disclosures are hereby incorporated by reference in their entirety. These arrays may generally be produced using methods known in the art, e.g., Fodor *et al.*, (1991) Science 251:767-777, which disclosure is hereby incorporated by reference in its entirety. The immobilization of arrays of oligonucleotides on solid supports has been rendered possible by the development of a technology generally identified as "Very Large Scale Immobilized Polymer Synthesis" (VLSIPS™) in which, typically, probes are immobilized in a high density array on a solid surface of a chip. Examples of VLSIPS™ technologies are provided in US Patents 5,143,854; and 5,412,087 and in PCT Publications WO 90/15070, WO 92/10092 and WO 95/11995, which disclosures are hereby incorporated by reference in their entirety. In designing strategies aimed at providing arrays of nucleotides immobilized on solid supports, further presentation strategies known in the art may be used, such as those disclosed in PCT Publications WO 94/12305, WO 94/11530, WO 97/29212 and WO 97/31256, the disclosures of which are incorporated herein by reference in their entirety.

Consequently, the invention concerns an array of nucleic acid molecules comprising at least one polynucleotide of the invention. Preferably, the invention concerns an array of nucleic acids comprising at least two polynucleotides of the invention, particularly probes or primers as described herein. Preferably, the invention concerns an array of nucleic acids comprising at least five polynucleotides of the invention, particularly probes or primers as described herein.

#### **Methods of making the polynucleotides of the invention**

The present invention also comprises methods of making the polynucleotides of the invention. Polynucleotides of the invention may be synthesized either enzymatically using techniques well known to those skilled in the art including amplification or hybridization-based methods as described herein, or chemically.

A variety of chemical methods of synthesizing nucleic acids are known to those skilled in the art. In many of these methods, synthesis is conducted on a solid support. Alternatively, polynucleotides may be prepared as described in U.S. Patent No. 5,049,656, which disclosure is hereby incorporated by reference in its entirety. In some embodiments, several polynucleotides prepared as described above are ligated together to generate longer polynucleotides having a desired sequence.

#### **POLYPEPTIDES OF THE INVENTION**

The term "GENSET polypeptides" is used herein to embrace all of the proteins and polypeptides of the present invention. The present invention encompasses GENSET polypeptides, including

recombinant, isolated or purified GENSET polypeptides consisting of: (a) the full length polypeptides of even SEQ ID NOs:2-112; (b) the full length polypeptides encoded by the clone inserts of the deposited clone pool; (c) the epitope-bearing fragments of the polypeptides of even SEQ ID NOs:2-112; (d) the epitope-bearing fragments of the polypeptides encoded by the clone inserts contained in the deposited clone pool; (e) the domains of the polypeptides of even SEQ ID NOs:2-112; (f) the domains of the polypeptides encoded by the clone inserts contained in the deposited clone pool; (g) the signal peptides of the polypeptides of even SEQ ID NOs:2-112 or encoded by the human cDNAs of the deposited clone pool; (h) the mature polypeptides of even SEQ ID Nos:2-112 or encoded by the human cDNAs of the deposited clone pool; and (i) the allelic variant polypeptides of any of the polypeptides of (a)-(f). Other objects of the invention are polypeptides encoded by the polynucleotides of the invention as well as fusion polypeptides comprising such polypeptides.

#### **Polypeptide variants**

The present invention further provides for GENSET polypeptides encoded by allelic and splice variants, orthologs, and/or species homologues. Procedures known in the art can be used to obtain, allelic variants, splice variants, orthologs, and/or species homologues of polynucleotides encoding polypeptides of the Sequence Listing and polypeptides encoded by the clone inserts of the deposited clone pool, using information from the sequences disclosed herein or the clones deposited with the ATCC.

The polypeptides of the present invention also include polypeptides having an amino acid sequence at least 50% identical, more preferably at least 60% identical, and still more preferably 70%, 80%, 90%, 95%, 96%, 97%, 98% or 99% identical to a polypeptide of the present invention. By a polypeptide having an amino acid sequence at least, for example, 95% "identical" to a query amino acid sequence of the present invention, it is intended that the amino acid sequence of the subject polypeptide is identical to the query sequence except that the subject polypeptide sequence may include up to five amino acid alterations per each 100 amino acids of the query amino acid sequence. In other words, to obtain a polypeptide having an amino acid sequence at least 95% identical to a query amino acid sequence, up to 5% (5 of 100) of the amino acid residues in the subject sequence may be inserted, deleted, (indels) or substituted with another amino acid.

Further polypeptides of the present invention include polypeptides which have at least 90% similarity, more preferably at least 95% similarity, and still more preferably at least 96%, 97%, 98% or 99% similarity to those described above. By a polypeptide having an amino acid sequence at least, for example, 95% "similar" to a query amino acid sequence of the present invention, it is intended that the amino acid sequence of the subject polypeptide is similar (i.e. contains identical or equivalent amino acid residues) to the query sequence except that the subject polypeptide sequence may include up to five amino acid alterations per each 100 amino acids of the query amino acid sequence. In other words, to obtain a polypeptide having an amino acid sequence at

least 95% similar to a query amino acid sequence, up to 5% (5 of 100) of the amino acid residues in the subject sequence may be inserted, deleted, (indels) or substituted with another non-equivalent amino acid.

These alterations of the reference sequence may occur at the amino or carboxy terminal positions of the reference amino acid sequence or anywhere between those terminal positions, interspersed either individually among residues in the reference sequence or in one or more contiguous groups within the reference sequence. The query sequence may be an entire amino acid sequence selected from the group consisting of polypeptide sequences of the Sequence Listing and those encoded by the clone inserts of the deposited clone pool or any fragment specified as described herein.

The variant polypeptides described herein are included in the present invention regardless of whether they have their normal biological activity. This is because even where a particular polypeptide molecule does not have biological activity, one of skill in the art would still know how to use the polypeptide, for instance, as a vaccine or to generate antibodies. Other uses of the polypeptides of the present invention that do not have GENSET biological activity include, *inter alia*, as epitope tags, in epitope mapping, and as molecular weight markers on SDS-PAGE gels or on molecular sieve gel filtration columns using methods known to those of skill in the art. As described below, the polypeptides of the present invention can also be used to raise polyclonal and monoclonal antibodies, which are useful in assays for detecting GENSET protein expression or as agonists and antagonists capable of enhancing or inhibiting GENSET protein function. Further, such polypeptides can be used in the yeast two-hybrid system to "capture" GENSET protein binding proteins, which are also candidate agonists and antagonists according to the present invention (*see, e.g.*, Fields and Song, (1989), *Nature*, 340: 245-246, which disclosure is hereby incorporated by reference in its entirety).

## 25 Preparation of the polypeptides of the invention

The polypeptides of the present invention can be prepared in any suitable manner known in the art. Such polypeptides include isolated naturally occurring polypeptides, recombinantly produced polypeptides, synthetically produced polypeptides, or polypeptides produced by a combination of these methods. The polypeptides of the present invention are preferably provided in an isolated form, and may be partially or preferably substantially purified. Consequently, the present invention also comprises methods of making the polypeptides of the invention.

### Isolation

#### From natural sources

The GENSET proteins of the invention may be isolated from natural sources, including bodily fluids, tissues and cells, whether directly isolated or cultured cells, of humans or non-human animals. Methods for extracting and purifying natural proteins are known in the art, and include the use of detergents or chaotropic agents to disrupt particles followed by differential extraction

and separation of the polypeptides by ion exchange chromatography, affinity chromatography, sedimentation according to density, and gel electrophoresis. See, for example, "Methods in Enzymology, Academic Press, 1993" for a variety of methods for purifying proteins, which disclosure is hereby incorporated by reference in its entirety. Polypeptides of the invention also  
5 can be purified from natural sources using antibodies directed against the polypeptides of the invention, such as those described herein, in methods which are well known in the art of protein purification.

From recombinant sources

Preferably, the GENSET polypeptides of the invention are recombinantly produced using  
10 routine expression methods known in the art. The polynucleotide encoding the desired polypeptide is operably linked to a promoter into an expression vector suitable for any convenient host. Both eukaryotic and prokaryotic host systems are used in forming recombinant polypeptides. The polypeptide is then isolated from lysed cells or from the culture medium and purified to the extent needed for its intended use.

15 Any polynucleotide of the present invention may be used to express GENSET polypeptides. The nucleic acid encoding the GENSET polypeptide to be expressed is operably linked to a promoter in an expression vector using conventional cloning technology. The GENSET insert in the expression vector may comprise the full coding sequence for the GENSET protein or a portion thereof.

20 Consequently, a further embodiment of the present invention is a method of making a polypeptide of the present invention, said method comprising the steps of:

- a) obtaining a cDNA comprising a sequence selected from the group consisting of:
  - i) the polynucleotide sequences of the Sequence Listing,
  - ii) the sequences of human cDNA clone inserts of the deposited clone pool,
  - 25 iii) polynucleotide sequences encoding one of the polypeptides of the Sequence Listing, and
  - iv) sequences of polynucleotides encoding a polypeptide which is encoded by one of the clone insert of the deposited clone pool;
- b) inserting said cDNA in an expression vector such that the cDNA is operably  
30 linked to a promoter; and
- c) introducing said expression vector into a host cell whereby said host cell produces said polypeptide.

In one aspect of this embodiment, the method further comprises the step of isolating the polypeptide. Another embodiment of the present invention is a polypeptide obtainable by the  
35 method described in the preceding paragraph.

The expression vector is any of the mammalian, yeast, insect or bacterial expression systems known in the art. Commercially available vectors and expression systems are available from a

variety of suppliers including Genetics Institute (Cambridge, MA), Stratagene (La Jolla, California), Promega (Madison, Wisconsin), and Invitrogen (San Diego, California). If desired, to enhance expression and facilitate proper protein folding, the codon context and codon pairing of the sequence is optimized for the particular expression organism in which the expression vector is introduced, as explained in U.S. Patent No. 5,082,767, which disclosure is hereby incorporated by reference in its entirety.

In one embodiment, the entire coding sequence of a GENSET cDNA and the 3'UTR through the poly A signal of the cDNA is operably linked to a promoter in the expression vector. Alternatively, if the nucleic acid encoding a portion of the GENSET protein lacks a methionine to serve as the initiation site, an initiating methionine can be introduced next to the first codon of the nucleic acid using conventional techniques. Similarly, if the insert from the GENSET cDNA lacks a poly A signal, this sequence can be added to the construct by, for example, splicing out the Poly A signal from pSG5 (Stratagene) using BglI and SalI restriction endonuclease enzymes and incorporating it into the mammalian expression vector pXT1 (Stratagene). pXT1 contains the LTRs and a portion of the gag gene from Moloney Murine Leukemia Virus. The position of the LTRs in the construct allows efficient stable transfection. The vector includes the Herpes Simplex Thymidine Kinase promoter and the selectable neomycin gene.

In another embodiment, it is often advantageous to add to the recombinant polynucleotide additional nucleotide sequence which codes for secretory or leader sequences, pro-sequences, sequences which aid in purification, such as multiple histidine residues, or an additional sequence for stability during recombinant production.

Transfection of a GENSET expression vector into mouse NTH 3T3 cells is but one embodiment of introducing polynucleotides into host cells. Introduction of a polynucleotide encoding a polypeptide into a host cell can be effected by calcium phosphate transfection, DEAE-dextran mediated transfection, cationic lipid-mediated transfection, electroporation, transduction, infection, or other methods. Such methods are described in many standard laboratory manuals, such as Davis *et al.*, (1986) Basic Methods in Molecular Biology, ed., Elsevier Press, NY, which disclosure is hereby incorporated by reference in its entirety. It is specifically contemplated that the polypeptides of the present invention may in fact be expressed by a host cell lacking a recombinant vector or naturally produced by a cell.

Alternatively, the GENSET polypeptide to be expressed may also be a product of transgenic animals, i.e., as a component of the milk of transgenic cows, goats, pigs or sheep which are characterized by somatic or germ cells containing a nucleotide sequence encoding the protein of interest.

A polypeptide of this invention can be recovered and purified from recombinant cell cultures by well-known methods including differential extraction, ammonium sulfate or ethanol precipitation, acid extraction, anion or cation exchange chromatography, phosphocellulose

chromatography, hydrophobic interaction chromatography, affinity chromatography, hydroxylapatite chromatography and lectin chromatography. See, for example, "Methods in Enzymology", *supra* for a variety of methods for purifying proteins. Most preferably, high performance liquid chromatography ("HPLC") is employed for purification. A recombinantly produced version of a GENSET polypeptide can be substantially purified using techniques described herein or otherwise known in the art, such as, for example, by the one-step method described in Smith and Johnson (1988) *Gene*. 67(1):31-40, which disclosure is hereby incorporated by reference in its entirety. Polypeptides of the invention also can be purified from recombinant sources using antibodies directed against the polypeptides of the invention, such as those described herein, in methods which are well known in the art of protein purification.

Preferably, the recombinantly expressed GENSET polypeptide is purified using standard immunochromatography techniques such as the one described in the section entitled "Immunoaffinity Chromatography". In such procedures, a solution containing the protein of interest, such as the culture medium or a cell extract, is applied to a column having antibodies against the protein attached to the chromatography matrix. The recombinant protein is allowed to bind the immunochromatography column. Thereafter, the column is washed to remove non-specifically bound proteins. The specifically bound secreted protein is then released from the column and recovered using standard techniques.

Depending upon the host employed in a recombinant production procedure, the polypeptides of the present invention may be glycosylated or may be non-glycosylated. In addition, polypeptides of the invention may also include an initial modified methionine residue, in some cases as a result of host-mediated processes. Thus, it is well known in the art that the N-terminal methionine encoded by the translation initiation codon generally is removed with high efficiency from any protein after translation in all eukaryotic cells. While the N-terminal methionine on most proteins also is efficiently removed in most prokaryotes, for some proteins, this prokaryotic removal process is inefficient, depending on the nature of the amino acid to which the N-terminal methionine is covalently linked. Thus, specifically included as an aspect of the invention are polypeptides of the present invention lacking the amino terminal methionine.

From chemical synthesis

In addition, polypeptides of the invention, especially short protein fragments, can be chemically synthesized using techniques known in the art [See, e.g., Creighton (1983), *Proteins: Structures and Molecular Principles*, W.H. Freeman & Co. 2nd Ed., T. E., New York; and Hunkapiller *et al.*, (1984) *Nature*. 310(5973):105-11], which disclosures are hereby incorporated by reference in their entireties. For example, a polypeptide corresponding to a fragment of a polypeptide sequence of the invention can be synthesized by use of a peptide synthesizer. Alternatively, the methods described in U.S. Patent No. 5,049,656, which disclosure is hereby incorporated by reference in its entirety, may be used.

Furthermore, if desired, nonclassical amino acids or chemical amino acid analogs can be introduced as a substitution or addition into the polypeptide sequence. Non-classical amino acids include, but are not limited to, to the D-isomers of the common amino acids, 2,4-diaminobutyric acid, a-amino isobutyric acid, 4-aminobutyric acid, Abu, 2-amino butyric acid, g-Abu, e-Ahx, 6-amino hexanoic acid, Aib, 2-amino isobutyric acid, 3-amino propionic acid, ornithine, norleucine, norvaline, hydroxyproline, sarcosine, citrulline, homocitrulline, cysteic acid, t-butylglycine, t-butylalanine, phenylglycine, cyclohexylalanine, b-alanine, fluoroamino acids, designer amino acids such as b-methyl amino acids, Ca-methyl amino acids, Na-methyl amino acids, and amino acid analogs in general. Furthermore, the amino acid can be D (dextrorotary) or L (levorotary).

#### 10 Modifications

The invention encompasses polypeptides which are differentially modified during or after translation, e.g., by glycosylation, acetylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to an antibody molecule or other cellular ligand, etc. Any of numerous chemical modifications may be carried out by known techniques, including, but not limited to, specific chemical cleavage by cyanogen bromide, trypsin, chymotrypsin, papain, V8 protease, NaBH<sub>4</sub>; acetylation, formylation, oxidation, reduction; metabolic synthesis in the presence of tunicamycin; etc.

Additional post-translational modifications encompassed by the invention include, for example, e.g., N-linked or O-linked carbohydrate chains, processing of N-terminal or C-terminal ends), attachment of chemical moieties to the amino acid backbone, chemical modifications of N-linked or O-linked carbohydrate chains, and addition or deletion of an N-terminal methionine residue as a result of prokaryotic host cell expression. The polypeptides may also be modified with a detectable label, such as an enzymatic, fluorescent, isotopic or affinity label to allow for detection and isolation of the protein.

Also provided by the invention are chemically modified derivatives of the polypeptides of the invention which may provide additional advantages such as increased solubility, stability and circulating time of the polypeptide, or decreased immunogenicity. See U.S. Patent No: 4,179,337. The chemical moieties for derivatization may be selected. See, U.S. Patent No: 4,179,337 which disclosure is hereby incorporated by reference in its entirety. The chemical moieties for derivatization may be selected from water soluble polymers such as polyethylene glycol, ethylene glycol/propylene glycol copolymers, carboxymethylcellulose, dextran, polyvinyl alcohol and the like. The polypeptides may be modified at random positions within the molecule, or at predetermined positions within the molecule and may include one, two, three or more attached chemical moieties.

The polymer may be of any molecular weight, and may be branched or unbranched. For polyethylene glycol, the preferred molecular weight is between about 1 kDa and about 100 kDa (the term "about" indicating that in preparations of polyethylene glycol, some molecules will

weigh more, some less, than the stated molecular weight) for ease in handling and manufacturing. Other sizes may be used, depending on the desired therapeutic profile (e.g., the duration of sustained release desired, the effects, if any on biological activity, the ease in handling, the degree or lack of antigenicity and other known effects of the polyethylene glycol to a therapeutic protein or analog).

The polyethylene glycol molecules (or other chemical moieties) should be attached to the protein with consideration of effects on functional or antigenic domains of the protein. There are a number of attachment methods available to those skilled in the art, e.g., EP 0 401 384, (coupling PEG to G-CSF), and Malik *et al.*, (1992), Exp. Hematol. 20:1028-1035 (reporting pegylation of GM-CSF using tresyl chloride), which disclosures are hereby incorporated by reference in their entireties. For example, polyethylene glycol may be covalently bound through amino acid residues via a reactive group, such as, a free amino or carboxyl group. Reactive groups are those to which an activated polyethylene glycol molecule may be bound. The amino acid residues having a free amino group may include lysine residues and the N-terminal amino acid residues; those having a free carboxyl group may include aspartic acid residues glutamic acid residues and the C-terminal amino acid residue. Sulfhydryl groups may also be used as a reactive group for attaching the polyethylene glycol molecules. Preferred for therapeutic purposes is attachment at an amino group, such as attachment at the N-terminus or lysine group.

One may specifically desire proteins chemically modified at the N-terminus. Using polyethylene glycol as an illustration of the present composition, one may select from a variety of polyethylene glycol molecules (by molecular weight, branching, etc.), the proportion of polyethylene glycol molecules to protein (polypeptide) molecules in the reaction mix, the type of pegylation reaction to be performed, and the method of obtaining the selected N-terminally pegylated protein. The method of obtaining the N-terminally pegylated preparation (i.e., separating this moiety from other monopegylated moieties if necessary) may be by purification of the N-terminally pegylated material from a population of pegylated protein molecules. Selective proteins chemically modified at the N-terminus modification may be accomplished by reductive alkylation, which exploits differential reactivity of different types of primary amino groups (lysine versus the N-terminal) available for derivatization in a particular protein. Under the appropriate reaction conditions, substantially selective derivatization of the protein at the N-terminus with a carbonyl group containing polymer is achieved.

#### Multimerization

The polypeptides of the invention may be in monomers or multimers (i.e., dimers, trimers, tetramers and higher multimers). Accordingly, the present invention relates to monomers and multimers of the polypeptides of the invention, their preparation, and compositions containing them. In specific embodiments, the polypeptides of the invention are monomers, dimers, trimers or tetramers. In additional embodiments, the multimers of the invention are at least dimers, at least

trimers, or at least tetramers.

Multimers encompassed by the invention may be homomers or heteromers. As used herein, the term "homomer", refers to a multimer containing only polypeptides corresponding to the amino acid sequences of the Sequence Listing or encoded by the human cDNA clone inserts of the deposited clone pool (including fragments, variants, splice variants, and fusion proteins, corresponding to these polypeptides as described herein). These homomers may contain polypeptides having identical or different amino acid sequences. In a specific embodiment, a homomer of the invention is a multimer containing only polypeptides having an identical amino acid sequence. In another specific embodiment, a homomer of the invention is a multimer containing polypeptides having different amino acid sequences. In specific embodiments, the multimer of the invention is a homodimer (*e.g.*, containing polypeptides having identical or different amino acid sequences) or a homotrimer (*e.g.*, containing polypeptides having identical and/or different amino acid sequences). In additional embodiments, the homomeric multimer of the invention is at least a homodimer, at least a homotrimer, or at least a homotetramer.

As used herein, the term "heteromer" refers to a multimer containing one or more heterologous polypeptides (*i.e.*, polypeptides of different proteins) in addition to the polypeptides of the invention. In a specific embodiment, the multimer of the invention is a heterodimer, a heterotrimer, or a heterotetramer. In additional embodiments, the heteromeric multimer of the invention is at least a heterodimer, at least a heterotrimer, or at least a heterotetramer.

Multimers of the invention may be the result of hydrophobic, hydrophilic, ionic and/or covalent associations and/or may be indirectly linked, by for example, liposome formation. Thus, in one embodiment, multimers of the invention, such as, for example, homodimers or homotrimers, are formed when polypeptides of the invention contact one another in solution. In another embodiment, heteromultimers of the invention, such as, for example, heterotrimers or heterotetramers, are formed when polypeptides of the invention contact antibodies to the polypeptides of the invention (including antibodies to the heterologous polypeptide sequence in a fusion protein of the invention) in solution. In other embodiments, multimers of the invention are formed by covalent associations with and/or between the polypeptides of the invention. Such covalent associations may involve one or more amino acid residues contained in the polypeptide sequence (*e.g.*, that recited in the sequence listing, or contained in the polypeptide encoded by a deposited clone). In one instance, the covalent associations are cross-linking between cysteine residues located within the polypeptide sequences, which interact in the native (*i.e.*, naturally occurring) polypeptide. In another instance, the covalent associations are the consequence of chemical or recombinant manipulation. Alternatively, such covalent associations may involve one or more amino acid residues contained in the heterologous polypeptide sequence in a fusion protein of the invention.

In one example, covalent associations are between the heterologous sequence contained in

a fusion protein of the invention (see, e.g., US Patent Number 5,478,925, which disclosure is hereby incorporated by reference in its entirety). In a specific example, the covalent associations are between the heterologous sequence contained in an Fc fusion protein of the invention (as described herein). In another specific example, covalent associations of fusion proteins of the invention are between heterologous polypeptide sequence from another protein that is capable of forming covalently associated multimers, such as for example, osteopontin (see, e.g., International Publication No: WO 98/49305, the contents of which are herein incorporated by reference in its entirety). In another embodiment, two or more polypeptides of the invention are joined through peptide linkers. Examples include those peptide linkers described in U.S. Pat. No. 5,073,627 (hereby incorporated by reference). Proteins comprising multiple polypeptides of the invention separated by peptide linkers may be produced using conventional recombinant DNA technology.

Another method for preparing multimer polypeptides of the invention involves the use of polypeptides of the invention fused to a leucine zipper or isoleucine zipper polypeptide sequence. Leucine zipper and isoleucine zipper domains are polypeptides that promote multimerization of the proteins in which they are found. Leucine zippers were originally identified in several DNA-binding proteins, and have since been found in a variety of different proteins [Landschulz *et al.*, (1988), *Science*. 240:1759]. Among the known leucine zippers are naturally occurring peptides and derivatives thereof that dimerize or trimerize. Examples of leucine zipper domains suitable for producing soluble multimeric proteins of the invention are those described in PCT application WO 94/10308, hereby incorporated by reference. Recombinant fusion proteins comprising a polypeptide of the invention fused to a polypeptide sequence that dimerizes or trimerizes in solution are expressed in suitable host cells, and the resulting soluble multimeric fusion protein is recovered from the culture supernatant using techniques known in the art.

Trimeric polypeptides of the invention may offer the advantage of enhanced biological activity. Preferred leucine zipper moieties and isoleucine moieties are those that preferentially form trimers. One example is a leucine zipper derived from lung surfactant protein D (SPD), as described in Hoppe *et al.*, (1994), *FEBS Letters*. 344:191 and in U.S. patent application Ser. No. 08/446,922, which disclosure is hereby incorporated by reference in its entirety. Other peptides derived from naturally occurring trimeric proteins may be employed in preparing trimeric polypeptides of the invention. In another example, proteins of the invention are associated by interactions between Flag® polypeptide sequence contained in fusion proteins of the invention containing Flag® polypeptide sequence. In a further embodiment, associations proteins of the invention are associated by interactions between heterologous polypeptide sequence contained in Flag® fusion proteins of the invention and anti Flag® antibody.

The multimers of the invention may be generated using chemical techniques known in the art. For example, polypeptides desired to be contained in the multimers of the invention may be

chemically cross-linked using linker molecules and linker molecule length optimization techniques known in the art (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety). Additionally, multimers of the invention may be generated using techniques known in the art to form one or more inter-molecule cross-links between the cysteine residues located within the sequence of the polypeptides desired to be contained in the multimer (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety). Further, polypeptides of the invention may be routinely modified by the addition of cysteine or biotin to the C terminus or N-terminus of the polypeptide and techniques known in the art may be applied to generate multimers containing one or more of these modified polypeptides (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety). Additionally, other techniques known in the art may be applied to generate liposomes containing the polypeptide components desired to be contained in the multimer of the invention (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety).

Alternatively, multimers of the invention may be generated using genetic engineering techniques known in the art. In one embodiment, polypeptides contained in multimers of the invention are produced recombinantly using fusion protein technology described herein or otherwise known in the art (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety). In a specific embodiment, polynucleotides coding for a homodimer of the invention are generated by ligating a polynucleotide sequence encoding a polypeptide of the invention to a sequence encoding a linker polypeptide and then further to a synthetic polynucleotide encoding the translated product of the polypeptide in the reverse orientation from the original C-terminus to the N-terminus (lacking the leader sequence) (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety). In another embodiment, recombinant techniques described herein or otherwise known in the art are applied to generate recombinant polypeptides of the invention which contain a transmembrane domain (or hydrophobic or signal peptide) and which can be incorporated by membrane reconstitution techniques into liposomes (see, e.g., US Patent Number 5,478,925, which is herein incorporated by reference in its entirety).

#### **Mutated polypeptides**

To improve or alter the characteristics of GENSET polypeptides of the present invention, protein engineering may be employed. Recombinant DNA technology known to those skilled in the art can be used to create novel mutant proteins or muteins including single or multiple amino acid substitutions, deletions, additions, or fusion proteins. Such modified polypeptides can show, e.g., increased/decreased biological activity or increased/decreased stability. In addition, they may be purified in higher yields and show better solubility than the corresponding natural polypeptide, at least under certain purification and storage conditions. Further, the polypeptides of the present invention may be produced as multimers including dimers, trimers and tetramers. Multimerization may be facilitated by linkers or recombinantly through heterologous polypeptides such as Fc

regions.

#### N- and C-terminal deletions

It is known in the art that one or more amino acids may be deleted from the N-terminus or C-terminus without substantial loss of biological function. [See, e.g., Ron *et al.*, (1993), Biol Chem., 268 2984-2988.] Accordingly, the present invention provides polypeptides having one or more residues deleted from the amino terminus. Similarly, many examples of biologically functional C-terminal deletion mutants are known (*see, e.g.,* Dobeli, *et al.* 1988). Accordingly, the present invention provides polypeptides having one or more residues deleted from the carboxy terminus. The invention also provides polypeptides having one or more amino acids deleted from both the amino and the carboxyl termini as described below.

#### Other mutations

Other mutants in addition to N- and C-terminal deletion forms of the protein discussed above are included in the present invention. Thus, the invention further includes variations of the GENSET polypeptides which show substantial GENSET polypeptide activity. Such mutants include deletions, insertions, inversions, repeats, and substitutions selected according to general rules known in the art so as to have little effect on activity.

There are two main approaches for studying the tolerance of an amino acid sequence to change [see, Bowie *et al.*, (1994), *Science*. 247:1306-1310, which disclosure is hereby incorporated by reference in its entirety]. The first method relies on the process of evolution, in which mutations are either accepted or rejected by natural selection. The second approach uses genetic engineering to introduce amino acid changes at specific positions of a cloned gene and selections or screens to identify sequences that maintain functionality. These studies have revealed that proteins are surprisingly tolerant of amino acid substitutions.

Typically seen as conservative substitutions are the replacements, one for another, among the aliphatic amino acids Ala, Val, Leu and Phe; interchange of the hydroxyl residues Ser and Thr, exchange of the acidic residues Asp and Glu, substitution between the amide residues Asn and Gln, exchange of the basic residues Lys and Arg and replacements among the aromatic residues Phe, Tyr. Thus, the polypeptide of the present invention may be, for example: (i) one in which one or more of the amino acid residues are substituted with a conserved or non-conserved amino acid residue (preferably a conserved amino acid residue) and such substituted amino acid residue may or may not be one encoded by the genetic code; or (ii) one in which one or more of the amino acid residues includes a substituent group; or (iii) one in which the GENSET polypeptide is fused with another compound, such as a compound to increase the half-life of the polypeptide (for example, polyethylene glycol); or (iv) one in which the additional amino acids are fused to the above form of the polypeptide, such as an IgG Fc fusion region peptide or leader or secretory sequence or a sequence which is employed for purification of the above form of the polypeptide or a pro-protein sequence.

Thus, the GENSET polypeptides of the present invention may include one or more amino acid substitutions, deletions, or additions, either from natural mutations or human manipulation. As indicated, changes are preferably of a minor nature, such as conservative amino acid substitutions that do not significantly affect the folding or activity of the protein. The following groups of amino acids represent equivalent changes: (1) Ala, Pro, Gly, Glu, Asp, Gln, Asn, Ser, Thr; (2) Cys, Ser, Tyr, Thr; (3) Val, Ile, Leu, Met, Ala, Phe; (4) Lys, Arg, His; (5) Phe, Tyr, Trp, His.

Furthermore, GENSET polypeptides of the present invention may include one or more amino acid substitutions that mimic modified amino acids. An example of this type of substitution includes replacing amino acids that are capable of being phosphorylated (e.g., serine, threonine, or tyrosine) with a negatively charged amino acid that resembles the negative charge of the phosphorylated amino acid (e.g., aspartic acid or glutamic acid). Also included is substitution of amino acids that are capable of being modified by hydrophobic groups (e.g., arginine) with amino acids carrying bulky hydrophobic side chains, such as tryptophan or phenylalanine. Therefore, a specific embodiment of the invention includes GENSET polypeptides that include one or more amino acid substitutions that mimic modified amino acids at positions where amino acids that are capable of being modified are normally positioned. Further included are GENSET polypeptides where any subset of modifiable amino acids are substituted. For example, a GENSET polypeptide that includes three serine residues may be substituted at any one, any two, or all three of said serines. Furthermore, any GENSET polypeptide amino acid capable of being modified may be excluded from substitution with a modification-mimicking amino acid.

A specific embodiment of a modified GENSET peptide molecule of interest according to the present invention, includes, but is not limited to, a peptide molecule which is resistant to proteolysis, is a peptide in which the -CONH- peptide bond is modified and replaced by a (CH<sub>2</sub>NH) reduced bond, a (NHCO) retro inverso bond, a (CH<sub>2</sub>-O) methylene-oxy bond, a (CH<sub>2</sub>-S) thiomethylene bond, a (CH<sub>2</sub>CH<sub>2</sub>) carba bond, a (CO-CH<sub>2</sub>) cetomethylene bond, a (CHOH-CH<sub>2</sub>) hydroxyethylene bond, a (N-N) bound, a E-alcene bond or also a -CH=CH- bond. The invention also encompasses a human GENSET polypeptide or a fragment or a variant thereof in which at least one peptide bond has been modified as described above.

Amino acids in the GENSET proteins of the present invention that are essential for function can be identified by methods known in the art, such as site-directed mutagenesis or alanine-scanning mutagenesis [see, e.g., Cunningham *et al.* (1989), Science 244:1081-1085, which disclosure is hereby incorporated by reference in its entirety]. Of special interest are substitutions of charged amino acids with other charged or neutral amino acids which may produce proteins with highly desirable improved characteristics, such as less aggregation. Aggregation may not only reduce activity but also be problematic when preparing pharmaceutical formulations, because aggregates can be immunogenic. [See, e.g., Pinckard *et al.*, (1967), Clin. Exp. Immunol 2:331-

340; Robbins *et al.*, (1987), Diabetes. 36:838-845; and Cleland *et al.*, (1993), Crit. Rev. Therapeutic Drug Carrier Systems. 10:307-377.]

A further embodiment of the invention relates to a polypeptide which comprises the amino acid sequence of a GENSET polypeptide having an amino acid sequence which contains at least  
 5 any one integer from 1 to 50 of conservative amino acid substitutions. Further included are polypeptides that contain not more than 40 conservative amino acid substitutions, not more than 30 conservative amino acid substitutions, and not more than 20 conservative amino acid substitutions. Also provided are polypeptides which comprise the amino acid sequence of a GENSET polypeptide, having at least one, but not more than 10, 9, 8, 7, 6, 5, 4, 3, 2 or 1 conservative amino  
 10 acid substitutions. Further provided are conservative amino acid substitutions at any appropriate position or combination of appropriate positions whereby all possible species are included as embodiments of the present invention. Each conservative substitution or combination of substitutions may also be excluded.

### **Polypeptide fragments**

#### **15 Structural definition**

The present invention is further directed to fragments of the polypeptides of the present invention. More specifically, the present invention embodies purified, isolated, and recombinant polypeptides comprising at least any one integer between 6 and 1000 (or the length of the polypeptides amino acid residues minus 1 if the length is less than 1000) of consecutive amino acid  
 20 residues. Preferably, the fragments are at least 6, preferably at least 8 to 10, more preferably 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 125, 150, 175, 200, 225, 250, 275, or 300 consecutive amino acids of a polypeptide of the present invention.

In addition to the above polypeptide fragments, further preferred sub-genuses of polypeptides comprise at least X amino acids, wherein "X" is defined as any integer between 6 and  
 25 the integer representing the C-terminal amino acid of the polypeptide of the present invention including the polypeptide sequences of the sequence listing below. Further included are species of polypeptide fragments at least 6 amino acids in length, as described above, that are further specified in terms of their N-terminal and C-terminal positions. However, included in the present invention as individual species are all polypeptide fragments, at least 6 amino acids in length, as  
 30 described above, and may be particularly specified by a N-terminal and C-terminal position. That is, every combination of a N-terminal and C-terminal position that a fragment at least 6 contiguous amino acid residues in length could occupy, on any given amino acid sequence of the sequence listing or of the present invention is included in the present invention

Further preferred polypeptide fragments comprising amino acids of the sequences of the  
 35 EVEN numbered SEQ ID NOs. of the Sequence listing, and polynucleotides encoding the same, are selected from the group consisting of amino acids consecutively numbered from 1-6, 1-7, 1-8, 1-9, 1-10, 1-11, 1-12, 1-13, 1-14, 1-15, 1-16, 1-17, 1-18, 1-19, 1-20, 1-21, 1-22, 1-23, 1-24, 1-25,

These specific embodiments, and other polypeptide and polynucleotide fragment  
 25 embodiments described herein may be modified as being “at least”, “equal to”, “equal to or less than”, “less than”, “at least \_\_\_ but not greater than \_\_\_” or “from \_\_\_ to \_\_\_”. a specified size or specified N-terminal and/or C-terminal positions. It is noted that all ranges used to describe any embodiment of the present invention are inclusive unless specifically set forth otherwise.

The present invention also provides for the exclusion of any individual fragment specified  
 30 by N-terminal and C-terminal positions or of any fragment specified by size in amino acid residues as described above. In addition, any number of fragments specified by N-terminal and C-terminal positions or by size in amino acid residues as described above may be excluded as individual species. Further, any number of fragments specified by N-terminal and C-terminal positions or by size in amino acid residues as described above may make up a polypeptide fragment in any  
 35 combination and may optionally include non-GENSET and GENSET-Related polypeptide sequences as well.

The above polypeptide fragments of the present invention can be immediately envisaged

using the above description and are therefore not individually listed solely for the purpose of not unnecessarily lengthening the specification. Moreover, the above fragments need not have a GENSET biological activity, although polypeptides having these activities are preferred embodiments of the invention, since they would be useful, for example, in immunoassays, in epitope mapping, epitope tagging, as vaccines, and as molecular weight markers. The above fragments may also be used to generate antibodies to a particular portion of the polypeptide. These antibodies can then be used in immunoassays well known in the art to distinguish between human and non-human cells and tissues or to determine whether cells or tissues in a biological sample are or are not of the same type which express the polypeptides of the present invention.

It is noted that the above species of polypeptide fragments of the present invention may alternatively be described by the formula "a to b"; where "a" equals the N-terminal most amino acid position and "b" equals the C-terminal most amino acid position of the polynucleotide; and further where "a" equals an integer between 1 and the number of amino acids of the polypeptide sequence of the present invention minus 6, and where "b" equals an integer between 7 and the number of amino acids of the polypeptide sequence of the present invention; and where "a" is an integer smaller than "b" by at least 6.

The present invention also provides for the exclusion of any species of polypeptide fragments of the present invention specified by 5' and 3' positions or sub-genuses of polypeptides specified by size in amino acids as described above. Any number of fragments specified by 5' and 3' positions or by size in amino acids, as described above, may be excluded.

#### Functional definition

##### Domains

Preferred polynucleotide fragments of the invention comprise domains of polypeptides of the invention. Such domains may eventually comprise linear or structural motifs and signatures including, but not limited to, leucine zippers, helix-turn-helix motifs, post-translational modification sites such as glycosylation sites, ubiquitination sites, alpha helices, and beta sheets, signal sequences encoding signal peptides which direct the secretion of the encoded proteins, sequences implicated in transcription regulation such as homeoboxes, acidic stretches, enzymatic active sites, substrate binding sites, and enzymatic cleavage sites. Such domains may present a particular biological activity such as DNA or RNA-binding, secretion of proteins, transcription regulation, enzymatic activity, substrate binding activity, etc.

In a preferred embodiment, domains comprise a number of amino acids that is any integer between 6 and 1000. Domains may be synthesized using any methods known to those skilled in the art, including those disclosed herein. Methods for determining the amino acids which make up a domain with a particular biological activity include mutagenesis studies and assays to determine the biological activity to be tested.

Alternatively, the polypeptides of the invention may be scanned for motifs, domains and/or

signatures in databases using any computer method known to those skilled in the art. Searchable databases include Prosite [Hofmann *et al.*, (1999) Nucl. Acids Res. 27:215-219; Bucher and Bairoch (1994) Proceedings 2nd International Conference on Intelligent Systems for Molecular Biology. Altman *et al.*, Eds., pp53-61, AAAIPress, Menlo Park], Pfam [Sonnhammer, *et al.*, (1997) Proteins. 28(3):405-20; Henikoff *et al.*, (2000) Electrophoresis 21(9):1700-6; Bateman *et al.*, (2000) Nucleic Acids Res. 28(1):263-6], Blocks [Henikoff *et al.*, (2000) Nucleic Acids Res. 28(1):228-30], Print [Attwood *et al.*, (1996) Nucleic Acids Res. 24(1):182-8], Prodom [Sonnhammer and Kahn, (1994) Protein Sci. 3(3):482-92; Corpet *et al.* (2000) Nucleic Acids Res. 28(1):267-9], Sbase [Pongor *et al.* (1993) Protein Eng. 6(4):391-5; Murvai *et al.*, (2000) Nucleic Acids Res. 28(1):260-2], Smart [Schultz *et al.* (1998) Proc Natl Acad Sci USA 95, 5857-5864], Dali/FSSP [Holm and Sander (1996) Nucleic Acids Res. 24(1):206-9, Holm and Sander (1997) Nucleic Acids Res. 25(1):231-4 and Holm and Sander (1999) Nucleic Acids Res. 27(1):244-7], HSSP [Sander and Schneider (1991) Proteins. 9(1):56-68.], CATH [Orengo *et al.*, (1997) Structure. 5(8):1093-108; Pearl *et al.*, (2000) Biochem Soc Trans. 28(2):269-75], SCOP [Murzin *et al.*, (1995) J Mol Biol. 247(4):536-40; Lo Conte *et al.*, (2000) Nucleic Acids Res. 28(1):257-9], COG [Tatusov *et al.* (1997), Science, 278, 631 :637 and Tatusov *et al.* (2000), Nucleic Acids Res. 28(1):33-6], specific family databases and derivatives thereof [Nevill-Manning *et al.*, (1998) Proc. Natl. Acad. Sci. U S A. 95, 5865-5871; Yona, *et al.* (1999), Proteins. 37(3):360-78; Attwood *et al.*, (2000) Nucleic Acids Res. 28(1):225-7], each of which disclosures are hereby incorporated by reference in their entirety. For a review on available databases, see issue 1 of volume 28 of Nucleic Acid Research (2000), which disclosure is hereby incorporated by reference in its entirety.

Epitopes and Antibody Fusions:

A preferred embodiment of the present invention is directed to epitope-bearing polypeptides and epitope-bearing polypeptide fragments. These epitopes may be "antigenic epitopes" or both an "antigenic epitope" and an "immunogenic epitope". An "immunogenic epitope" is defined as a part of a protein that elicits an antibody response *in vivo* when the polypeptide is the immunogen. On the other hand, a region of polypeptide to which an antibody binds is defined as an "antigenic determinant" or "antigenic epitope." The number of immunogenic epitopes of a protein generally is less than the number of antigenic epitopes [see, e.g., Geysen *et al.*, (1984), Proc. Natl. Acad. Sci. U.S.A. 81:3998-4002, which disclosure is hereby incorporated by reference in its entirety]. It is particularly noted that although a particular epitope may not be immunogenic, it is nonetheless useful since antibodies can be made to both immunogenic and antigenic epitopes. When the antigen is a polypeptide, it is customary to classify epitopes as being linear (i.e., composed of a contiguous sequence of amino acids repeated along the polypeptide chain) or nonlinear (i.e., composed of amino acids brought into proximity as a result of the folding of the polypeptide chain). Nonlinear epitopes are also called "conformational" because they arise through the folding of the polypeptide chain into a particular conformation, i.e.,

a distinctive 3-D shape.

An epitope can comprise as few as 3 amino acids in a spatial conformation, which is unique to the epitope. Generally an epitope consists of at least 6 such amino acids, and more often at least 8-10 such amino acids. In preferred embodiment, antigenic epitopes comprise a number of amino acids that is any integer between 3 and 50. Fragments which function as epitopes may be produced by any conventional means [*see, e.g.*, Houghten (1985), Proc. Natl. Acad. Sci. USA 82:5131-5135], also further described in U.S. Patent No. 4,631,21, which disclosures are hereby incorporated by reference in their entireties. Methods for determining the amino acids which make up an epitope include x-ray crystallography, 2-dimensional nuclear magnetic resonance, and epitope mapping, e.g., the Pepscan method described by Geysen, *et al.* (1984); PCT Publication No. WO 84/03564; and PCT Publication No. WO 84/03506, which disclosures are hereby incorporated by reference in their entireties. Nonlinear epitopes are determined by methods such as protein footprinting (U.S. Patent 5,691,448, which disclosure is hereby incorporated by reference in its entirety). Another example is the algorithm of Jameson and Wolf, (1988), Comp. Appl. Biosci. 4:181-186 (said reference incorporated by reference in its entirety). The Jameson-Wolf antigenic analysis, for example, may be performed using the computer program PROTEAN, using default parameters (Version 4.0 Windows, DNASTAR, Inc., 1228 South Park Street Madison, WI.

All fragments of the polypeptides of the present invention, at least 6 amino acids residues in length, are included in the present invention as being useful as antigenic linear epitopes. Amino acid residues comprising other immunogenic epitopes may be determined by Jameson-Wolf analysis, by other similar algorithms, or by *in vivo* testing for an antigenic response using the methods described herein or those known in the art. Immunogenic epitopes predicted by algorithm analysis describe only amino acid residues comprising linear epitopes predicted to have the highest degree of immunogenicity. Polypeptides of the present invention that are not specifically described as immunogenic are not considered non-antigenic as they may be antigenic *in vivo*. Alternatively, the polypeptides are most likely antigenic *in vitro* using methods such as phage display.

Preferably, the epitope-containing polypeptide comprises a contiguous span of at least 6, preferably at least 8 to 10, more preferably 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 125, 150, 175, 200, 225, 250, 275, or 300 amino acids of a polypeptide of the present invention.

Nonlinear epitopes comprise more than one noncontiguous polypeptide sequence of at least one amino acid each. Such epitopes result from noncontiguous polypeptides brought into proximity by secondary, tertiary, or quaternary structural features. Therefore, the present invention encompasses isolated, purified, or recombinant polypeptides and fragments thereof which comprise a nonlinear epitope. Preferred polypeptides providing nonlinear epitopes are formed by a contiguous surface of natively folded protein and are thus at least 10 amino acids in length, further

preferably 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 125, 150, 175, 200, 225, 250, 275, or 300 amino acids of a polypeptide of the present invention, to the extent that a contiguous span of these lengths is consistent with the lengths of said selected sequence. Further preferred polypeptides comprise full-length polypeptide sequences selected from the group consisting of the polypeptide sequences of the Sequence Listing. Additionally, nonlinear epitopes may be formed by synthetic peptides that mimic an antigenic site or contiguous surface normally presented on a protein in the native conformation. Therefore, preferred polypeptides providing nonlinear epitopes may be formed by synthetic proteins that comprise a combination of at least 5, 6, 7, 8, 9, 10, 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, 100, 125, 150, 175, 200, 225, 250, 275, or 300 amino acids.

10 The epitope-bearing fragments of the present invention preferably comprise 6 to 50 amino acids (i.e. any integer between 6 and 50, inclusive) of a polypeptide of the present invention. Also, included in the present invention are antigenic fragments between the integers of 6 and the full length GENSET sequence of the sequence listing. All combinations of sequences between the integers of 6 and the full-length sequence of a GENSET polypeptide are included. The epitope-bearing fragments may be specified by either the number of contiguous amino acid residues (as a sub-genus) or by specific N-terminal and C-terminal positions (as species) as described above for the polypeptide fragments of the present invention. Any number of epitope-bearing fragments of the present invention may also be excluded in the same manner.

Antigenic epitopes are useful, for example, to raise antibodies, including monoclonal antibodies that specifically bind the epitope (see, Wilson *et al.*, 1984; and Sutcliffe *et al.*, (1983), Science. 219:660-666, which disclosures are hereby incorporated by reference in their entireties). The antibodies are then used in various techniques such as diagnostic and tissue/cell identification techniques, as described herein, and in purification methods such as immunoaffinity chromatography.

25 Similarly, immunogenic epitopes can be used to induce antibodies according to methods well known in the art (see, Sutcliffe *et al.*, supra; Wilson *et al.*, supra; Chow *et al.*, (1985), Proc. Natl. Acad. Sci. USA. 82:910-914; and Bittle *et al.*, (1985), *Viol.* 66:2347-2354, which disclosures are hereby incorporated by reference in their entireties). A preferred immunogenic epitope includes the natural GENSET protein. The immunogenic epitopes may be presented together with a carrier protein, such as an albumin, to an animal system (such as rabbit or mouse) or, if it is long enough (at least about 25 amino acids), without a carrier. However, immunogenic epitopes comprising as few as 8 to 10 amino acids have been shown to be sufficient to raise antibodies capable of binding to, at the very least, linear epitopes in a denatured polypeptide (e.g., in Western blotting).

35 Epitope-bearing polypeptides of the present invention are used to induce antibodies according to methods well known in the art including, but not limited to, *in vivo* immunization, *in vitro* immunization, and phage display methods (see, e.g., Sutcliffe, *et al.*, supra; Wilson, *et al.*,

*supra*, and Bittle, *et al.*, *supra*). If *in vivo* immunization is used, animals may be immunized with free peptide; however, anti-peptide antibody titer may be boosted by coupling of the peptide to a macromolecular carrier, such as keyhole limpet hemacyanin (KLH) or tetanus toxoid. For instance, peptides containing cysteine residues may be coupled to a carrier using a linker such as -maleimidobenzoyl- N-hydroxysuccinimide ester (MBS), while other peptides may be coupled to carriers using a more general linking agent such as glutaraldehyde. Animals such as rabbits, rats and mice are immunized with either free or carrier-coupled peptides, for instance, by intraperitoneal and/or intradermal injection of emulsions containing about 100 µg of peptide or carrier protein and Freund's adjuvant. Several booster injections may be needed, for instance, at intervals of about two weeks, to provide a useful titer of anti-peptide antibody, which can be detected, for example, by ELISA assay using free peptide adsorbed to a solid surface. The titer of anti-peptide antibodies in serum from an immunized animal may be increased by selection of anti-peptide antibodies, for instance, by adsorption to the peptide on a solid support and elution of the selected antibodies according to methods well known in the art.

As one of skill in the art will appreciate, and discussed above, the polypeptides of the present invention comprising an immunogenic or antigenic epitope can be fused to heterologous polypeptide sequences. For example, the polypeptides of the present invention may be fused with the constant domain of immunoglobulins (IgA, IgE, IgG, IgM), or portions thereof (CH1, CH2, CH3, any combination thereof including both entire domains and portions thereof) resulting in chimeric polypeptides. These fusion proteins facilitate purification, and show an increased half-life *in vivo*. This has been shown, *e.g.*, for chimeric proteins consisting of the first two domains of the human CD4-polypeptide and various domains of the constant regions of the heavy or light chains of mammalian immunoglobulins [*see, e.g.*, EPA 0,394,827; and Traunecker *et al.*, (1988), *Nature*. 331:84-86, which disclosures are hereby incorporated by reference in their entirety]. Fusion proteins that have a disulfide-linked dimeric structure due to the IgG portion can also be more efficient in binding and neutralizing other molecules than monomeric polypeptides or fragments thereof alone [*see, e.g.*, Fountoulakis *et al.*, (1995) *Biochem.* 270:3958-3964, which disclosure is hereby incorporated by reference in its entirety]. Nucleic acids encoding the above epitopes can also be recombined with a gene of interest as an epitope tag to aid in detection and purification of the expressed polypeptide.

Additional fusion proteins of the invention may be generated through the techniques of gene-shuffling, motif-shuffling, exon-shuffling, or codon-shuffling (collectively referred to as "DNA shuffling"). DNA shuffling may be employed to modulate the activities of polypeptides of the present invention thereby effectively generating agonists and antagonists of the polypeptides. See, for example, U.S. Patent Nos.: 5,605,793; 5,811,238; 5,834,252; 5,837,458; and Patten, *et al.* (1997), *Curr Opin Biotechnol.* 8:724-733; Harayama (1998), *Trends Biotechnol.* 16(2): 76-82; Hansson *et al.*, (1999), *J. Mol. Biol.* 287:265-276; and Lorenzo and Blasco (1998) *Biotechniques*.

24(2):308-313. (Each of these documents are hereby incorporated by reference). In one embodiment, one or more components, motifs, sections, parts, domains, fragments, etc., of coding polynucleotides of the invention, or the polypeptides encoded thereby may be recombined with one or more components, motifs, sections, parts, domains, fragments, etc. of one or more heterologous molecules.

The present invention further encompasses any combination of the polypeptide fragments listed in this section.

## **Antibodies**

### Definitions

10 The present invention further relates to antibodies and T-cell antigen receptors (TCR), which specifically bind the polypeptides, and more specifically, the epitopes of the polypeptides of the present invention. The antibodies of the present invention include IgG (including IgG1, IgG2, IgG3, and IgG4), IgA (including IgA1 and IgA2), IgD, IgE, or IgM, and IgY. The term "antibody" (Ab) refers to a polypeptide or group of polypeptides which are comprised of at least one binding domain, where a binding domain is formed from the folding of variable domains of an antibody molecule to form three-dimensional binding spaces with an internal surface shape and charge distribution complementary to the features of an antigenic determinant of an antigen, which allows an immunological reaction with the antigen. As used herein, the term "antibody" is meant to include whole antibodies, including single-chain whole antibodies, and antigen binding fragments thereof. In a preferred embodiment the antibodies are human antigen binding antibody fragments of the present invention include, but are not limited to, Fab, Fab' F(ab)2 and F(ab')2, Fd, single-chain Fvs (scFv), single-chain antibodies, disulfide-linked Fvs (sdFv) and fragments comprising either a V<sub>L</sub> or V<sub>H</sub> domain. The antibodies may be from any animal origin including birds and mammals. Preferably, the antibodies are human, murine, rabbit, goat, guinea pig, camel, horse, or chicken.

Antigen-binding antibody fragments, including single-chain antibodies, may comprise the variable region(s) alone or in combination with the entire or partial of the following: hinge region, CH1, CH2, and CH3 domains. Also included in the invention are any combinations of variable region(s) and hinge region, CH1, CH2, and CH3 domains. The present invention further includes chimeric, humanized, and human monoclonal and polyclonal antibodies, which specifically bind the polypeptides of the present invention. The present invention further includes antibodies that are anti-idiotypic to the antibodies of the present invention.

The antibodies of the present invention may be monospecific, bispecific, and trispecific or have greater multispecificity. Multispecific antibodies may be specific for different epitopes of a polypeptide of the present invention or may be specific for both a polypeptide of the present invention as well as for heterologous compositions, such as a heterologous polypeptide or solid support material. *See, e.g.*, WO 93/17715; WO 92/08802; WO 91/00360; WO 92/05793; Tutt, *et*

*al.*, (1991), *J. Immunol.* 147:60-69; US Patents 5,573,920, 4,474,893, 5,601,819, 4,714,681, 4,925,648; Kostelny *et al.*, (1992), *J. Immunol.* 148:1547-1553, which disclosures are hereby incorporated by reference in their entirety.

Antibodies of the present invention may be described or specified in terms of the epitope(s) or epitope-bearing portion(s) of a polypeptide of the present invention, which are recognized or specifically bound by the antibody. The antibodies may specifically bind a complete protein encoded by a nucleic acid of the present invention, or a fragment thereof. Therefore, the epitope(s) or epitope bearing polypeptide portion(s) may be specified as described herein, *e.g.*, by N-terminal and C-terminal positions, by size in contiguous amino acid residues, or otherwise described herein (including the sequence listing). Antibodies which specifically bind any epitope or polypeptide of the present invention may also be excluded as individual species. Therefore, the present invention includes antibodies that specifically bind specified polypeptides of the present invention, and allows for the exclusion of the same.

Thus, another embodiment of the present invention is a purified or isolated antibody capable of specifically binding to a polypeptide of the present invention. In one aspect of this embodiment, the antibody is capable of binding to a linear epitope-containing polypeptide comprising at least 6 consecutive amino acids, preferably at least 8 to 10 consecutive amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 consecutive amino acids of a polypeptides of the present invention. In another aspect of this embodiment, the antibody is capable of binding to a nonlinear epitope-containing polypeptide comprising 10 amino acids in length, further preferably 12, 15, 20, 25, 30, 35, 40, 50, 60, 75, or 100 amino acids, further preferably, a contiguous surface of the native conformation of a polypeptide of the present application. Additionally, the antibody is capable of binding a nonlinear epitope presented by a synthetic peptide designed to mimic a contiguous surface of the native conformation of a polypeptide of a sequence selected from the group consisting of GENSET polypeptides. Antibodies that bind linear epitopes may be used in combination with antibodies that bind nonlinear epitopes for instance, in assays that detect proper protein folding.

Antibodies of the present invention may also be described or specified in terms of their cross-reactivity. Antibodies that do not specifically bind any other analog, ortholog, or homologue of the polypeptides of the present invention are included. Antibodies that do not bind polypeptides with less than 95%, less than 90%, less than 85%, less than 80%, less than 75%, less than 70%, less than 65%, less than 60%, less than 55%, and less than 50% identity (as calculated using methods known in the art and described herein, *e.g.*, using FASTDB and the parameters set forth herein) to a polypeptide of the present invention are also included in the present invention. Further included in the present invention are antibodies, which only bind polypeptides encoded by polynucleotides, which hybridize to a polynucleotide of the present invention under stringent hybridization conditions (as described herein). Antibodies of the present invention may also be

described or specified in terms of their binding affinity. Preferred binding affinities include those with a dissociation constant or  $K_d$  less than  $5 \times 10^{-6}M$ ,  $10^{-6}M$ ,  $5 \times 10^{-7}M$ ,  $10^{-7}M$ ,  $5 \times 10^{-8}M$ ,  $10^{-8}M$ ,  $5 \times 10^{-9}M$ ,  $10^{-9}M$ ,  $5 \times 10^{-10}M$ ,  $10^{-10}M$ ,  $5 \times 10^{-11}M$ ,  $10^{-11}M$ ,  $5 \times 10^{-12}M$ ,  $10^{-12}M$ ,  $5 \times 10^{-13}M$ ,  $10^{-13}M$ ,  $5 \times 10^{-14}M$ ,  $10^{-14}M$ ,  $5 \times 10^{-15}M$ , and  $10^{-15}M$ .

- 5 The invention also concerns a purified or isolated antibody capable of specifically binding to a mutated GENSET protein or to a fragment or variant thereof comprising an epitope of the mutated GENSET protein.

#### Preparation of antibodies

- The antibodies of the present invention may be prepared by any suitable method known in the art. Some of these methods are described in more detail in the example entitled "Example 1: Preparation of Antibody Compositions to the GENSET protein". For example, a polypeptide of the present invention or an antigenic fragment thereof can be administered to an animal in order to induce the production of sera containing "polyclonal antibodies". As used herein, the term "monoclonal antibody" is not limited to antibodies produced through hybridoma technology but it rather refers to an antibody that is derived from a single clone, including eukaryotic, prokaryotic, or phage clone, and not the method by which it is produced. Monoclonal antibodies can be prepared using a wide variety of techniques known in the art including the use of hybridoma, recombinant, and phage display technology.

- Hybridoma techniques include those known in the art [see, e.g., Harlow and Lane, (1988) Antibodies A Laboratory Manual. Cold Spring Harbor Laboratory. pp. 53-242; Hammerling (1981), Monoclonal Antibodies and T-Cell Hybridomas, Elsevier, N.Y. 563-681; said references incorporated by reference in their entireties]. Fab and F(ab')<sub>2</sub> fragments may be produced, for example, from hybridoma-produced antibodies by proteolytic cleavage, using enzymes such as papain (to produce Fab fragments) or pepsin (to produce F(ab')<sub>2</sub> fragments).

- Alternatively, antibodies of the present invention can be produced through the application of recombinant DNA technology or through synthetic chemistry using methods known in the art. For example, the antibodies of the present invention can be prepared using various phage display methods known in the art. In phage display methods, functional antibody domains are displayed on the surface of a phage particle, which carries polynucleotide sequences encoding them. Phage with a desired binding property are selected from a repertoire or combinatorial antibody library (e.g. human or murine) by selecting directly with antigen, typically antigen bound or captured to a solid surface or bead. Phage used in these methods are typically filamentous phage including fd and M13 with Fab, Fv or disulfide stabilized Fv antibody domains recombinantly fused to either the phage gene III or gene VIII protein. Examples of phage display methods that can be used to make the antibodies of the present invention include those disclosed in Brinkman *et al.*, (1995) J. Immunol Methods, 182:41-50; Ames *et al.*, (1995), J. Immunol. Meth., 184:177-186.; Kettleborough *et al.*, (1994), Eur. J. Immunol., 24:952-958; Persic *et al.*, (1997), Gene, 1879-81;

Burton *et al.* (1994), Adv. Immunol., 57:191-280; PCT/GB91/01134; WO 90/02809; WO 91/10737; WO 92/01047; WO 92/18619; WO 93/11236; WO 95/15982; WO 95/20401; and US Patents 5,698,426, 5,223,409, 5,403,484, 5,580,717, 5,427,908, 5,750,753, 5,821,047, 5,571,698, 5,427,908, 5,516,637, 5,780,225, 5,658,727 and 5,733,743 (said references incorporated by  
5 reference in their entireties).

As described in the above references, after phage selection, the antibody coding regions from the phage can be isolated and used to generate whole antibodies, including human antibodies, or any other desired antigen binding fragment, and expressed in any desired host including mammalian cells, insect cells, plant cells, yeast, and bacteria. For example, techniques to  
10 recombinantly produce Fab, Fab' F(ab)2 and F(ab')2 fragments can also be employed using methods known in the art such as those disclosed in WO 92/22324; Mullinax *et al.*, (1992), BioTechniques. 12(6):864-869; and Sawai *et al.*, (1995), AJRI 34:26-34; and Better *et al.*, (1988), Science. 240:1041-1043 (said references incorporated by reference in their entireties).

Examples of techniques which can be used to produce single-chain Fvs and antibodies  
15 include those described in U.S. Patents 4,946,778 and 5,258,498; Huston *et al.*, (1991), Meth. Enzymol. 203:46-88; Shu, *et al.*, (1993), Proc. Natl. Acad. Sci. U.S.A. 90:7995-7999; and Skerra, *et al.*, (1988), Science 240:1038-1040, which disclosures are hereby incorporated by reference in their entireties. For some uses, including *in vivo* use of antibodies in humans and *in vitro* detection assays, it may be preferable to use chimeric, humanized, or human antibodies. Methods for  
20 producing chimeric antibodies are known in the art. See e.g., Morrison, (1985); Oi *et al.*, (1986), BioTechniques 4:214; Gillies *et al.*, (1989), J. Immunol Methods. 125:191-202; and US Patent 5,807,715, which disclosures are hereby incorporated by reference in their entireties. Antibodies can be humanized using a variety of techniques including CDR-grafting (EP 0 239 400; WO 91/09967; US Patent 5,530,101; and 5,585,089), veneering or resurfacing [EP 0 592 106; EP 0 519  
25 596; Padlan (1991), Molec. Immunol. 28(4/5):489-498; Studnicka *et al.*, (1994), Protein Engineering. 7(6):805-814; Roguska *et al.*, (1994), Proc. Natl. Acad. Sci. U.S.A. 91:969-973], and chain shuffling (US Patent 5,565,332), which disclosures are hereby incorporated by reference in their entireties. Human antibodies can be made by a variety of methods known in the art including phage display methods described above. See also, US Patents 4,444,887, 4,716,111, 5,545,806,  
30 and 5,814,318; WO 98/46645; WO 98/50433; WO 98/24893; WO 96/34096; WO 96/33735; and WO 91/10741 (said references incorporated by reference in their entireties).

Further included in the present invention are antibodies recombinantly fused or chemically conjugated (including both covalent and non-covalent conjugations) to a polypeptide of the present invention. The antibodies may be specific for antigens other than polypeptides of the present  
35 invention. For example, antibodies of the present invention may be recombinantly fused or conjugated to molecules useful as labels in detection assays and effector molecules such as heterologous polypeptides, drugs, or toxins. See, e.g., WO 92/08495; WO 91/14438; WO

89/12624; US Patent 5,314,995; and EP 0 396 387, which disclosures are hereby incorporated by reference in their entireties. Fused antibodies may also be used to target the polypeptides of the present invention to particular cell types, either *in vitro* or *in vivo*, by fusing or conjugating the polypeptides of the present invention to antibodies specific for particular cell surface receptors.

5 Antibodies fused or conjugated to the polypeptides of the present invention may also be used in *vitro* immunoassays and purification methods using methods known in the art [*see e.g.*, Harbor, *et al. supra*; WO 93/21232; EP 0 439 095; Naramura *et al.*, (1994), Immunol. Lett. 39:91-99; US Patent 5,474,981; Gillies *et al.*, (1992), Proc Natl Acad Sci U S A 89:1428-1432; Fell *et al.*, (1991), J. Immunol. 146:2446-2452; said references incorporated by reference in their entireties].

10 The present invention further includes compositions comprising the polypeptides of the present invention fused or conjugated to antibody domains other than the variable regions. For example, the polypeptides of the present invention may be fused or conjugated to an antibody Fc region, or portion thereof. The antibody portion fused to a polypeptide of the present invention may comprise the hinge region, CH1 domain, CH2 domain, and CH3 domain or any combination  
15 of whole domains or portions thereof. The polypeptides of the present invention may be fused or conjugated to the above antibody portions to increase the *in vivo* half-life of the polypeptides or for use in immunoassays using methods known in the art. The polypeptides may also be fused or conjugated to the above antibody portions to form multimers. For example, Fc portions fused to the polypeptides of the present invention can form dimers through disulfide bonding between the  
20 Fc portions. Higher multimeric forms can be made by fusing the polypeptides to portions of IgA and IgM. Methods for fusing or conjugating the polypeptides of the present invention to antibody portions are known in the art. *See e.g.*, US Patents 5,336,603, 5,622,929, 5,359,046, 5,349,053, 5,447,851, 5,112,946; EP 0 307 434, EP 0 367 166; WO 96/04388, WO 91/06570; Ashkenazi *et al.*, (1991), Proc. Natl. Acad. Sci. USA 88:10535-10539; Zheng, X.X., *et al.* (1995), J. Immunol.  
25 154:5590-5600; and Vil, *et al.* (1992), Proc Natl Acad Sci U S A 89:11337-11341 (said references incorporated by reference in their entireties).

Non-human animals or mammals, whether wild-type or transgenic, which express a different species of GENSET than the one to which antibody binding is desired, and animals which do not express GENSET (i.e. a GENSET knock out animal as described herein) are particularly  
30 useful for preparing antibodies. GENSET knock out animals will recognize all or most of the exposed regions of a GENSET protein as foreign antigens, and therefore produce antibodies with a wider array of GENSET epitopes. Moreover, smaller polypeptides with only 10 to 30 amino acids may be useful in obtaining specific binding to any one of the GENSET proteins. In addition, the humoral immune system of animals which produce a species of GENSET that resembles the  
35 antigenic sequence will preferentially recognize the differences between the animal's native GENSET species and the antigen sequence, and produce antibodies to these unique sites in the antigen sequence. Such a technique will be particularly useful in obtaining antibodies that

specifically bind to any one of the GENSET proteins.

A preferred embodiment of the invention is a method of specifically binding an antibody or antibody fragment to a GENSET polypeptide. This method comprises the step of contacting a GENSET polypeptide-specific antibody or fragment thereof with a GENSET polypeptide under  
5 antibody-binding conditions. Further included is a method of specifically binding an antibody or antibody fragment to an epitope, domain, or fragment of a GENSET polypeptide. This method may be used to, for example, detect, purify, or modify the activity of GENSET polypeptides, as discussed herein.

Antibodies of the invention can be used to assay protein levels in a test sample or  
10 biological sample using methods known to those of skill in the art. Antibody-based methods useful for detecting protein include immunoassays, such as the enzyme linked immunosorbent assay (ELISA) and radioimmunoassay (RIA). Suitable antibody assay labels are known in the art and include enzyme labels, such as glucose oxidase, horseradish peroxidase, and alkaline phosphatase; radioisotopes, such as iodine (125I, 121I), carbon (14C), sulfur (35S), tritium (3H),  
15 indium (121In), and technetium (99Tc); luminescent labels, such luminol, isolumino, thiomalic acridinium ester, imidazole, acridinium salt, oxalate ester, luciferin, luciferase, and aequorin; and fluorescent labels, such as fluorescein isothiocyanate, rhodamine, phycoerythrin, phycocyanin, allophycocyanin, o-phthaldehyde, and fluorescamine.

#### USES OF POLYNUCLEOTIDES

##### 20 **Uses of polynucleotides as reagents**

The polynucleotides of the present invention may be used as reagents in isolation procedures, diagnostic assays, and forensic procedures. For example, sequences from the GENSET polynucleotides of the invention may be detectably labeled and used as probes to isolate other sequences capable of hybridizing to them. In addition, sequences from the GENSET  
25 polynucleotides of the invention may be used to design PCR primers to be used in isolation, diagnostic, or forensic procedures.

##### To find corresponding genomic DNA sequences

The GENSET cDNAs of the invention may also be used to clone sequences located upstream of the cDNAs of the invention on the corresponding genomic DNA. Such upstream  
30 sequences may be capable of regulating gene expression, including promoter sequences, enhancer sequences, and other upstream sequences which influence transcription or translation levels. Once identified and cloned, these upstream regulatory sequences may be used in expression vectors designed to direct the expression of an inserted gene in a desired spatial, temporal, developmental, or quantitative fashion.

##### 35 Use of cDNAs or Fragments thereof to Clone Upstream Sequences from Genomic DNA

Sequences derived from polynucleotides of the inventions may be used to isolate the promoters of the corresponding genes using chromosome walking techniques. In one chromosome

walking technique, the GenomeWalker™ kit available from Clontech is used according to the manufacturer's instructions.

Identification of Promoters in Cloned Upstream Sequences

Once the upstream genomic sequences have been cloned and sequenced, prospective  
5 promoters and transcription start sites within the upstream sequences may be identified by comparing the sequences upstream of the polynucleotides of the inventions with databases containing known transcription start sites, transcription factor binding sites, or promoter sequences.

In addition, promoters in the upstream sequences may be identified using promoter reporter vectors as follows. The expression of the reporter gene will be detected when placed  
10 under the control of regulatory active polynucleotide fragments or variants of the GENSET promoter region located upstream of the first exon of the GENSET gene. Suitable promoter reporter vectors, into which the GENSET promoter sequences may be cloned include pSEAP-Basic, pSEAP-Enhancer, pβgal-Basic, pβgal-Enhancer, or pEGFP-1 Promoter Reporter vectors available from Clontech, or pGL2-basic or pGL3-basic promoterless luciferase reporter gene  
15 vector from Promega. Briefly, each of these promoter reporter vectors include multiple cloning sites positioned upstream of a reporter gene encoding a readily assayable protein such as secreted alkaline phosphatase, luciferase, beta-galactosidase, or green fluorescent protein. The sequences upstream the GENSET coding region are inserted into the cloning sites upstream of the reporter gene in both orientations and introduced into an appropriate host cell. The level of reporter protein  
20 is assayed and compared to the level obtained from a vector which lacks an insert in the cloning site. The presence of an elevated expression level in the vector containing the insert with respect to the control vector indicates the presence of a promoter in the insert. If necessary, the upstream sequences can be cloned into vectors which contain an enhancer for increasing transcription levels from weak promoter sequences. A significant level of expression above that observed with the  
25 vector lacking an insert indicates that a promoter sequence is present in the inserted upstream sequence. Promoter sequence within the upstream genomic DNA may be further defined by site directed mutagenesis, linker scanning analysis, or other techniques familiar to those skilled in the art.

The strength and the specificity of the promoter of each GENSET gene can be assessed  
30 through the expression levels of a detectable polynucleotide operably linked to the GENSET promoter in different types of cells and tissues. The detectable polynucleotide may be either a polynucleotide that specifically hybridizes with a predefined oligonucleotide probe, or a polynucleotide encoding a detectable protein, including a GENSET polypeptide or a fragment or a variant thereof. This type of assay is well known to those skilled in the art and is described in US  
35 Patent No. 5,502,176; and US Patent No. 5,266,488; the disclosures of which are incorporated by reference herein in their entirety. Some of the methods are discussed in more detail elsewhere in the application.

The promoters and other regulatory sequences located upstream of the polynucleotides of the inventions may be used to design expression vectors capable of directing the expression of an inserted gene in a desired spatial, temporal, developmental, or quantitative manner. A promoter capable of directing the desired spatial, temporal, developmental, and quantitative patterns may be selected using the results of the expression analysis described herein. For example, if a promoter which confers a high level of expression in muscle is desired, the promoter sequence upstream of a polynucleotide of the invention derived from an mRNA which is expressed at a high level in muscle may be used in the expression vector.

#### To find similar sequences

Polynucleotides of the invention may be used to isolate and/or purify nucleic acids similar thereto using any methods well known to those skilled in the art including the techniques based on hybridization or on amplification described in this section. These methods may be used to obtain the genomic DNAs which encode the mRNAs from which the GENSET cDNAs are derived, mRNAs corresponding to GENSET cDNAs, or nucleic acids which are homologous to GENSET cDNAs or fragments thereof, such as variants, species homologues or orthologs.

#### Hybridization-based methods

Techniques for identifying cDNA clones in a cDNA library which hybridize to a given probe sequence are disclosed in Sambrook *et al.*, (1989) Molecular Cloning: A Laboratory Manual. (2ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, New York), and in Hames and Higgins (1985) Nucleic Acid Hybridization: A Practical Approach (Hames and Higgins Ed., IRL Press, Oxford), the disclosures of which are incorporated herein by reference in their entireties. The same techniques may be used to isolate genomic DNAs.

A probe comprising at least 10 consecutive nucleotides from a GENSET cDNA or fragment thereof is labeled with a detectable label such as a radioisotope or a fluorescent molecule.

Techniques for labeling the probe are well known and include phosphorylation with polynucleotide kinase, nick translation, *in vitro* transcription, and non radioactive techniques. The cDNAs or genomic DNAs in the library are transferred to a nitrocellulose or nylon filter and denatured. After blocking of nonspecific sites, the filter is incubated with the labeled probe for an amount of time sufficient to allow binding of the probe to cDNAs or genomic DNAs containing a sequence capable of hybridizing thereto.

By varying the stringency of the hybridization conditions used to identify cDNAs or genomic DNAs which hybridize to the detectable probe, cDNAs or genomic DNAs having different levels of identity to the probe can be identified and isolated as described below.

#### Stringent conditions

"Stringent hybridization conditions" are defined as conditions in which only nucleic acids having a high level of identity to the probe are able to hybridize to said probe. These conditions may be calculated as follows:

For probes between 14 and 70 nucleotides in length the melting temperature ( $T_m$ ) is calculated using the formula:  $T_m = 81.5 + 16.6(\log(Na^+)) + 0.41(\text{fraction G+C}) - (600/N)$  where N is the length of the probe.

If the hybridization is carried out in a solution containing formamide, the melting temperature may be calculated using the equation:  $T_m = 81.5 + 16.6(\log(Na^+)) + 0.41(\text{fraction G+C}) - (0.63\% \text{ formamide}) - (600/N)$  where N is the length of the probe.

Prehybridization may be carried out in 6X SSC, 5X Denhardt's reagent, 0.5% SDS, 100  $\mu$ g denatured fragmented salmon sperm DNA or 6X SSC, 5X Denhardt's reagent, 0.5% SDS, 100  $\mu$ g denatured fragmented salmon sperm DNA, 50% formamide. The formulas for SSC and Denhardt's solutions are listed in Sambrook *et al.*, 1986.

Hybridization is conducted by adding the detectable probe to the prehybridization solutions listed above. Where the probe comprises double stranded DNA, it is denatured before addition to the hybridization solution. The filter is contacted with the hybridization solution for a sufficient period of time to allow the probe to hybridize to nucleic acids containing sequences complementary thereto or homologous thereto. For probes over 200 nucleotides in length, the hybridization may be carried out at 15-25°C below the  $T_m$ . For shorter probes, such as oligonucleotide probes, the hybridization may be conducted at 15-25°C below the  $T_m$ . Preferably, for hybridizations in 6X SSC, the hybridization is conducted at approximately 68°C. Preferably, for hybridizations in 50% formamide containing solutions, the hybridization is conducted at approximately 42°C.

Following hybridization, the filter is washed in 2X SSC, 0.1% SDS at room temperature for 15 minutes. The filter is then washed with 0.1X SSC, 0.5% SDS at room temperature for 30 minutes to 1 hour. Thereafter, the solution is washed at the hybridization temperature in 0.1X SSC, 0.5% SDS. A final wash is conducted in 0.1X SSC at room temperature.

Nucleic acids which have hybridized to the probe are identified by autoradiography or other conventional techniques.

#### *Low and moderate conditions*

Changes in the stringency of hybridization and signal detection are primarily accomplished through the manipulation of formamide concentration (lower percentages of formamide result in lowered stringency); salt conditions, or temperature. The above procedure may thus be modified to identify nucleic acids having decreasing levels of identity to the probe sequence. For example, the hybridization temperature may be decreased in increments of 5°C from 68°C to 42°C in a hybridization buffer having a sodium concentration of approximately 1M. Following hybridization, the filter may be washed with 2X SSC, 0.5% SDS at the temperature of hybridization. These conditions are considered to be "moderate" conditions above 50°C and "low" conditions below 50°C. Alternatively, the hybridization may be carried out in buffers, such as 6X SSC, containing formamide at a temperature of 42°C. In this case, the concentration of formamide

in the hybridization buffer may be reduced in 5% increments from 50% to 0% to identify clones having decreasing levels of identity to the probe. Following hybridization, the filter may be washed with 6X SSC, 0.5% SDS at 50°C. These conditions are considered to be "moderate" conditions above 25% formamide and "low" conditions below 25% formamide. cDNAs or  
 5 genomic DNAs which have hybridized to the probe are identified by autoradiography or other conventional techniques.

Note that variations in the above conditions may be accomplished through the inclusion and/or substitution of alternate blocking reagents used to suppress background in hybridization experiments. Typical blocking reagents include Denhardt's reagent, BLOTTO, heparin, denatured  
 10 salmon sperm DNA, and commercially available proprietary formulations. The inclusion of specific blocking reagents may require modification of the hybridization conditions described above, due to problems with compatibility.

Consequently, the present invention encompasses methods of isolating nucleic acids similar to the polynucleotides of the invention, comprising the steps of:

- 15 a) contacting a collection of cDNA or genomic DNA molecules with a detectable probe comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40 or 50 consecutive nucleotides of a polynucleotide of the present invention under stringent, moderate or low conditions which permit said probe to hybridize to at least a cDNA or genomic DNA molecule in said collection;
- 20 b) identifying said cDNA or genomic DNA molecule which hybridizes to said detectable probe; and
- c) isolating said cDNA or genomic DNA molecule which hybridized to said probe.

PCR-based methods

In addition to the above described methods, other protocols are available to obtain  
 25 homologous cDNAs using GENSET cDNA of the present invention or fragment thereof as outlined in the following paragraphs.

cDNAs may be prepared by obtaining mRNA from the tissue, cell, or organism of interest using mRNA preparation procedures utilizing polyA selection procedures or other techniques known to those skilled in the art. A first primer capable of hybridizing to the polyA tail of the  
 30 mRNA is hybridized to the mRNA and a reverse transcription reaction is performed to generate a first cDNA strand.

The term "capable of hybridizing to the polyA tail of said mRNA" refers to and embraces all primers containing stretches of thymidine residues, so-called oligo(dT) primers, that hybridize to the 3' end of eukaryotic poly(A)+ mRNAs to prime the synthesis of a first cDNA strand.  
 35 Techniques for generating said oligo (dT) primers and hybridizing them to mRNA to subsequently prime the reverse transcription of said hybridized mRNA to generate a first cDNA strand are well known to those skilled in the art and are described in Current Protocols in Molecular Biology, John

Wiley and Sons, Inc. 1997 and Sambrook, *et al.*, 1989. Preferably, said oligo (dT) primers are present in a large excess in order to allow the hybridization of all mRNA 3'ends to at least one oligo (dT) molecule. The priming and reverse transcription steps are preferably performed between 37°C and 55°C depending on the type of reverse transcriptase used. Preferred oligo(dT) primers for priming reverse transcription of mRNAs are oligonucleotides containing a stretch of thymidine residues of sufficient length to hybridize specifically to the polyA tail of mRNAs, preferably of 12 to 18 thymidine residues in length. More preferably, such oligo(T) primers comprise an additional sequence upstream of the poly(dT) stretch in order to allow the addition of a given sequence to the 5'end of all first cDNA strands which may then be used to facilitate subsequent manipulation of the cDNA. Preferably, this added sequence is 8 to 60 residues in length. For instance, the addition of a restriction site in 5' of cDNAs facilitates subcloning of the obtained cDNA. Alternatively, such an added 5' end may also be used to design primers of PCR to specifically amplify cDNA clones of interest.

The first cDNA strand is then hybridized to a second primer. Any appropriate polynucleotide fragment of the invention may be used. This second primer contains at least 10 consecutive nucleotides of a polynucleotide of the invention. Preferably, the primer comprises at least 10, 12, 15, 17, 18, 20, 23, 25, or 28 consecutive nucleotides of a polynucleotide of the invention. In some embodiments, the primer comprises more than 30 nucleotides of a polynucleotide of the invention. If it is desired to obtain cDNAs containing the full protein coding sequence, including the authentic translation initiation site, the second primer used contains sequences located upstream of the translation initiation site. The second primer is extended to generate a second cDNA strand complementary to the first cDNA strand. Alternatively, RT-PCR may be performed as described above using primers from both ends of the cDNA to be obtained.

The double stranded cDNAs made using the methods described above are isolated and cloned. The cDNAs may be cloned into vectors such as plasmids or viral vectors capable of replicating in an appropriate host cell. For example, the host cell may be a bacterial, mammalian, avian, or insect cell.

Techniques for isolating mRNA, reverse transcribing a primer hybridized to mRNA to generate a first cDNA strand, extending a primer to make a second cDNA strand complementary to the first cDNA strand, isolating the double stranded cDNA and cloning the double stranded cDNA are well known to those skilled in the art and are described in *Current Protocols in Molecular Biology*, John Wiley & Sons, Inc. 1997 and Sambrook, *et al.*, 1989.

Consequently, the present invention encompasses methods of making cDNAs. In a first embodiment, the method of making a cDNA comprises the steps of:

- a) contacting a collection of mRNA molecules from human cells with a primer comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of a sequence selected from the group consisting of the polynucleotide

sequences complementary to the polynucleotide sequences of the Sequence Listing and those complementary to a human cDNA clone insert of the deposited clone pool;

- b) hybridizing said primer to an mRNA in said collection;
- 5 c) reverse transcribing said hybridized primer to make a first cDNA strand from said mRNA;
- d) making a second cDNA strand complementary to said first cDNA strand; and
- e) isolating the resulting cDNA comprising said first cDNA strand and said second cDNA strand.

10 Another embodiment of the present invention is a purified cDNA obtainable by the method of the preceding paragraph. In one aspect of this embodiment, the cDNA encodes at least a portion of a human polypeptide.

In a second embodiment, the method of making a cDNA comprises the steps of:

- 15 a) contacting a collection of mRNA molecules from human cells with a first primer capable of hybridizing to the polyA tail of said mRNA;
- b) hybridizing said first primer to said polyA tail;
- c) reverse transcribing said mRNA to make a first cDNA strand;
- d) making a second cDNA strand complementary to said first cDNA strand using at least one primer comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of a sequence selected from the group consisting of polynucleotide sequences of the Sequence Listing and those of human cDNA clone inserts of the deposited clone pool; and
- 20 e) isolating the resulting cDNA comprising said first cDNA strand and said second cDNA strand.

25 In another aspect of this method the second cDNA strand is made by:

- a) contacting said first cDNA strand with a second primer comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of a sequence selected from the group consisting of polynucleotide sequences of the Sequence Listing and those of human cDNA clone inserts of the deposited clone pool, and a third primer which sequence is fully included within the sequence of said first primer;
- 30 b) performing a first polymerase chain reaction with said second and third primers to generate a first PCR product;
- c) contacting said first PCR product with a fourth primer, comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of said sequence selected from the group consisting of polynucleotide sequences of the Sequence Listing and those of human cDNA clone inserts of the deposited clone pool, and a fifth primer, which sequence is fully included within the sequence of said third
- 35

primer, wherein said fourth and fifth hybridize to sequences within said first PCR product; and

- d) performing a second polymerase chain reaction, thereby generating a second PCR product.

5 Alternatively, the second cDNA strand may be made by contacting said first cDNA strand with a second primer comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of a sequence selected from the group consisting of polynucleotide sequences of the Sequence Listing and human cDNA clone inserts of the deposited clone pool, and a third primer which sequence is fully included within the sequence of said first primer and performing a  
10 polymerase chain reaction with said second and third primers to generate said second cDNA strand.

Alternatively, the second cDNA strand may be made by:

- a) contacting said first cDNA strand with a second primer comprising at least 12, 15, 18, 20, 23, 25, 28, 30, 35, 40, or 50 consecutive nucleotides of a sequence selected  
15 from the group consisting of polynucleotide sequences of the Sequence Listing and human cDNA clone inserts of the deposited clone pool;
- b) hybridizing said second primer to said first strand cDNA; and
- c) extending said hybridized second primer to generate said second cDNA strand.

Another embodiment of the present invention is a purified cDNA obtainable by a method  
20 of making a cDNA of the invention. In one aspect of this embodiment, said cDNA encodes at least a portion of a human polypeptide.

#### Other protocols

Alternatively, other procedures may be used for obtaining homologous cDNAs. In one approach, cDNAs are prepared from mRNA and cloned into double stranded phagemids as  
25 follows. The cDNA library in the double stranded phagemids is then rendered single stranded by treatment with an endonuclease, such as the Gene II product of the phage F1 and an exonuclease [Chang *et al.*, (1993) Gene 127:95-8, which disclosure is hereby incorporated by reference in its entirety]. A biotinylated oligonucleotide comprising the sequence of a fragment of a known GENSET cDNA, genomic DNA or fragment thereof is hybridized to the single stranded  
30 phagemids. Preferably, the fragment comprises at least 10, 12, 15, 17, 18, 20, 23, 25, or 28 consecutive nucleotides of a polynucleotide of the present invention.

Hybrids between the biotinylated oligonucleotide and phagemids are isolated by incubating the hybrids with streptavidin coated paramagnetic beads and retrieving the beads with a magnet [Fry *et al.*, (1992) Biotechniques, 13: 124-131, which disclosure is hereby incorporated by  
35 reference in its entirety]. Thereafter, the resulting phagemids are released from the beads and converted into double stranded DNA using a primer specific for the GENSET cDNA or fragment used to design the biotinylated oligonucleotide. Alternatively, protocols such as the Gene Trapper

kit (Gibco BRL), which disclosure is hereby incorporated by reference in its entirety, may be used. The resulting double stranded DNA is transformed into bacteria. Homologous cDNAs to the GENSET cDNA or fragment thereof sequence are identified by colony PCR or colony hybridization.

5 As a chromosome marker

GENSET polynucleotides may be mapped to their chromosomal locations using any methods or techniques known to those skilled in the art including radiation hybrid (RH) mapping, PCR-based mapping and Fluorescence in situ hybridization (FISH) mapping described below.

Radiation hybrid mapping

- 10 Radiation hybrid (RH) mapping is a somatic cell genetic approach that can be used for high resolution mapping of the human genome. [See, e.g., Benham *et al.* (1989) *Genomics* 4:509-517 and Cox *et al.*, (1990) *Science* 250:245-250; and Schuler *et al.*, (1996) *Science* 274:540-546], which disclosure is hereby incorporated by reference in its entirety.]

Mapping of cDNAs to Human Chromosomes using PCR techniques

- 15 GENSET cDNAs and genomic DNAs may be assigned to human chromosomes using PCR based methodologies. In such approaches, oligonucleotide primer pairs are designed from the cDNA sequence to minimize the chance of amplifying through an intron. Preferably, the oligonucleotide primers are 18-23 bp in length and are designed for PCR amplification. The creation of PCR primers from known sequences is well known to those with skill in the art. For a  
20 review of PCR technology see Erlich (1992), which disclosure is hereby incorporated by reference in its entirety.

- PCR is used to screen a series of somatic cell hybrid cell lines containing defined sets of human chromosomes for the presence of a given cDNA or genomic DNA. DNA is isolated from the somatic hybrids and used as starting templates for PCR reactions using the primer pairs from  
25 the GENSET cDNAs or genomic DNAs. Only those somatic cell hybrids with chromosomes containing the human gene corresponding to the GENSET cDNA or genomic DNA will yield an amplified fragment. The GENSET cDNAs or genomic DNAs are assigned to a chromosome by analysis of the segregation pattern of PCR products from the somatic hybrid DNA templates. The single human chromosome present in all cell hybrids that give rise to an amplified fragment is the  
30 chromosome containing that GENSET cDNA or genomic DNA. For a review of techniques and analysis of results from somatic cell gene mapping experiments, see Ledbetter *et al.*, (1990) *Genomics* 6:475-481, which disclosure is hereby incorporated by reference in its entirety.

Mapping of cDNAs to Chromosomes Using Fluorescence in situ Hybridization

- Fluorescence *in situ* hybridization (FISH) allows the GENSET cDNA or genomic DNA to  
35 be mapped to a particular location on a given chromosome. The chromosomes to be used for fluorescence in situ hybridization techniques may be obtained from a variety of sources including cell cultures, tissues, or whole blood.

In a preferred embodiment, chromosomal localization of a GENSET cDNA or genomic DNA is obtained by FISH as described by Cherif *et al.*, (1990), "Simultaneous Localization of Cosmids and Chromosome R-Banding by Fluorescence Microscopy: Application to Regional Mapping of Human Chromosome 11", Proc. Natl. Acad. Sci. U.S.A., 87:6639-6643, which disclosure is hereby incorporated by reference in its entirety. For chromosomal localization, fluorescent R-bands are obtained as previously described (Cherif, *et al.*, 1990, *supra*).

Use of cDNAs to Construct or Expand Chromosome Maps

Once the GENSET cDNAs or genomic DNAs have been assigned to particular chromosomes using any technique known to those skilled in the art those skilled in the art, particularly those described herein, they may be utilized to construct a high resolution map of the chromosomes on which they are located or to identify the chromosomes in a sample.

Chromosome mapping involves assigning a given unique sequence to a particular chromosome as described above. Once the unique sequence has been mapped to a given chromosome, it is ordered relative to other unique sequences located on the same chromosome. One approach to chromosome mapping utilizes a series of yeast artificial chromosomes (YACs) bearing several thousand long inserts derived from the chromosomes of the organism from which the GENSET cDNAs or genomic DNAs are obtained. This approach is described in Nagaraja *et al.*, (1997) "X chromosome map at 75-kb STS resolution, revealing extremes of recombination and GC content", Genome Res. 1997 Mar;7(3):210-22, which disclosure is hereby incorporated by reference in its entirety.

Identification of genes associated with hereditary diseases or drug response

This example illustrates an approach useful for the association of GENSET cDNAs or genomic DNAs with particular phenotypic characteristics. In this example, a particular GENSET cDNA or genomic DNA is used as a test probe to associate that GENSET cDNA or genomic DNA with a particular phenotypic characteristic.

GENSET cDNAs or genomic DNAs are mapped to a particular location on a human chromosome using techniques such as those described herein or other techniques known in the art. A search of Mendelian Inheritance in Man (V. McKusick, Mendelian Inheritance in Man; available on line through Johns Hopkins University Welch Medical Library) reveals the region of the human chromosome which contains the GENSET cDNA or genomic DNA to be a very gene rich region containing several known genes and several diseases or phenotypes for which genes have not been identified. The gene corresponding to this GENSET cDNA or genomic DNA thus becomes an immediate candidate for each of these genetic diseases.

Cells from patients with these diseases or phenotypes are isolated and expanded in culture. PCR primers from the GENSET cDNA or genomic DNA are used to screen genomic DNA, mRNA or cDNA obtained from the patients. GENSET cDNAs or genomic DNAs that are not amplified in the patients can be positively associated with a particular disease by further analysis.

Alternatively, the PCR analysis may yield fragments of different lengths when the samples are derived from an individual having the phenotype associated with the disease than when the sample is derived from a healthy individual, indicating that the gene containing the cDNA may be responsible for the genetic disease.

5

### Uses of polynucleotides in recombinant vectors

The present invention also relates to recombinant vectors including the isolated polynucleotides of the present invention, and to host cells recombinant for a polynucleotide of the invention, such as the above vectors, as well as to methods of making such vectors and host cells and for using them for production of GENSET polypeptides by recombinant techniques.

### Recombinant Vectors

The term "vector" is used herein to designate either a circular or a linear DNA or RNA molecule, which is either double-stranded or single-stranded, and which comprise at least one polynucleotide of interest that is sought to be transferred in a cell host or in a unicellular or multicellular host organism. The present invention encompasses a family of recombinant vectors that comprise a regulatory polynucleotide and/or a coding polynucleotide derived from either the GENSET genomic sequence or the cDNA sequence. Generally, a recombinant vector of the invention may comprise any of the polynucleotides described herein, including regulatory sequences, coding sequences and polynucleotide constructs, as well as any GENSET primer or probe as defined herein.

In a first preferred embodiment, a recombinant vector of the invention is used to amplify the inserted polynucleotide derived from a GENSET genomic sequence or a GENSET cDNA, for example any cDNA selected from the group consisting of polynucleotide sequences of the Sequence Listing, those of human cDNA clone inserts of the deposited clone pool, variants and fragments thereof in a suitable cell host, this polynucleotide being amplified at every time that the recombinant vector replicates.

A second preferred embodiment of the recombinant vectors according to the invention comprises expression vectors comprising either a regulatory polynucleotide or a coding nucleic acid of the invention, or both. Within certain embodiments, expression vectors are employed to express a GENSET polypeptide which can be then purified and, for example be used in ligand screening assays or as an immunogen in order to raise specific antibodies directed against the GENSET protein. In other embodiments, the expression vectors are used for constructing transgenic animals and also for gene therapy. Expression requires that appropriate signals are provided in the vectors, said signals including various regulatory elements, such as enhancers/promoters from both viral and mammalian sources that drive expression of the genes of interest in host cells. Dominant drug selection markers for establishing permanent, stable cell clones expressing the products are generally included in the expression vectors of the invention, as

they are elements that link expression of the drug selection markers to expression of the polypeptide.

More particularly, the present invention relates to expression vectors which include nucleic acids encoding a GENSET protein, preferably a GENSET protein with an amino acid sequence selected from the group consisting of polypeptide sequences of the Sequence Listing, those encoded by the human cDNA clone inserts of the deposited clone pool, variants and fragments thereof. The polynucleotides of the present invention may be used to express an encoded protein in a host organism to produce a beneficial effect. In such procedures, the encoded protein may be transiently expressed in the host organism or stably expressed in the host organism. The encoded protein may have any of the activities described herein. The encoded protein may be a protein which the host organism lacks or, alternatively, the encoded protein may augment the existing levels of the protein in the host organism.

Some of the elements which can be found in the vectors of the present invention are described in further detail in the following sections.

15 General features of the expression vectors of the invention

A recombinant vector according to the invention comprises, but is not limited to, a YAC (Yeast Artificial Chromosome), a BAC (Bacterial Artificial Chromosome), a phage, a phagemid, a cosmid, a plasmid or even a linear DNA molecule which may comprise a chromosomal, non-chromosomal, semi-synthetic and synthetic DNA. Such a recombinant vector can comprise a transcriptional unit comprising an assembly of:

- (1) a genetic element or elements having a regulatory role in gene expression, for example promoters or enhancers. Enhancers are cis-acting elements of DNA, usually from about 10 to 300 bp in length that act on the promoter to increase the transcription.
- 25 (2) a structural or coding sequence which is transcribed into mRNA and eventually translated into a polypeptide, said structural or coding sequence being operably linked to the regulatory elements described in (1); and
- (3) appropriate transcription initiation and termination sequences. Structural units intended for use in yeast or eukaryotic expression systems preferably include a leader sequence enabling extracellular secretion of translated protein by a host cell. Alternatively, when a recombinant protein is expressed without a leader or transport sequence, it may include a N-terminal residue. This residue may or may not be subsequently cleaved from the expressed recombinant protein to provide a final product.

35 Generally, recombinant expression vectors will include origins of replication, selectable markers permitting transformation of the host cell, and a promoter derived from a highly expressed gene to direct transcription of a downstream structural sequence. The heterologous structural

sequence is assembled in appropriate phase with translation initiation and termination sequences, and preferably a leader sequence capable of directing secretion of the translated protein into the periplasmic space or the extracellular medium. In a specific embodiment wherein the vector is adapted for transfecting and expressing desired sequences in mammalian host cells, preferred  
5 vectors will comprise an origin of replication in the desired host, a suitable promoter and enhancer, and also any necessary ribosome binding sites, polyadenylation signals, splice donor and acceptor sites, transcriptional termination sequences, and 5'-flanking non-transcribed sequences. DNA sequences derived from the SV40 viral genome, for example SV40 origin, early promoter, enhancer, splice and polyadenylation signals may be used to provide the required non-transcribed  
10 genetic elements.

The *in vivo* expression of a GENSET polypeptide of the present invention may be useful in order to correct a genetic defect related to the expression of the native gene in a host organism, for the treatment or prevention of any disease or condition that can be treated or prevented by increasing the level of GENSET polypeptide expression, or to the production of a biologically  
15 inactive GENSET protein. Consequently, the present invention also comprises recombinant expression vectors mainly designed for the *in vivo* production of a GENSET polypeptide the present invention by the introduction of the appropriate genetic material in the organism or the patient to be treated. This genetic material may be introduced *in vitro* in a cell that has been previously extracted from the organism, the modified cell being subsequently reintroduced in the  
20 said organism, directly *in vivo* into the appropriate tissue.

#### Regulatory Elements

The suitable promoter regions used in the expression vectors according to the present invention are chosen taking into account the cell host in which the heterologous gene has to be expressed.

25 A suitable promoter may be heterologous with respect to the nucleic acid for which it controls the expression or alternatively can be endogenous to the native polynucleotide containing the coding sequence to be expressed. Additionally, the promoter is generally heterologous with respect to the recombinant vector sequences within which the construct promoter/coding sequence has been inserted. Promoter regions can be selected from any desired gene using, for example,  
30 CAT (chloramphenicol transferase) vectors and more preferably pKK232-8 and pCM7 vectors.

Preferred bacterial promoters are the LacI, LacZ, the T3 or T7 bacteriophage RNA polymerase promoters, the gpt, lambda PR, PL and trp promoters (EP 0036776), the polyhedrin promoter, or the p10 protein promoter from baculovirus (Kit Novagen) [Smith *et al.*, (1983) Mol. Cell. Biol. 3:2156-2165; O'Reilly *et al.* (1992), "Baculovirus Expression Vectors: A Laboratory  
35 Manual", W. H. Freeman and Co., New York; which disclosures are hereby incorporated by reference in their entireties], the lambda PR promoter or also the trc promoter.

Eukaryotic promoters include CMV immediate early, HSV thymidine kinase, early and

late SV40, LTRs from retrovirus, and mouse metallothionein-L. Selection of a convenient vector and promoter is well within the level of ordinary skill in the art.

*Other regulatory elements*

Where a cDNA insert is employed, one will typically desire to include a polyadenylation signal to effect proper polyadenylation of the gene transcript. Also contemplated as an element of the expression cassette is a terminator. These elements can serve to enhance message levels and to minimize read through from the cassette into other sequences.

Selectable Markers

Selectable markers confer an identifiable change to the cell permitting easy identification of cells containing the expression construct. The selectable marker genes for selection of transformed host cells are preferably dihydrofolate reductase or neomycin resistance for eukaryotic cell culture, TRP1 for *S. cerevisiae* or tetracycline, rifampicin or ampicillin resistance in *E. Coli*, or levan saccharase for mycobacteria, this latter marker being a negative selection marker.

Preferred Vectors

15 *Bacterial vectors*

As a representative but non-limiting example, useful expression vectors for bacterial use can comprise a selectable marker and a bacterial origin of replication derived from commercially available plasmids comprising genetic elements of pBR322 (ATCC 37017). Such commercial vectors include, for example, pKK223-3 (Pharmacia, Uppsala, Sweden), and pGEM1 (Promega Biotec, Madison, WI, USA). Large numbers of other suitable vectors are known to those of skill in the art, and commercially available, such as the following bacterial vectors: pQE70, pQE60, pQE-9 (Qiagen), pbs, pD10, phagescript, psiX174, pbluescript SK, pbsks, pNH8A, pNH16A, pNH18A, pNH46A (Stratagene); ptrc99a, pKK223-3, pKK233-3, pDR540, pRIT5 (Pharmacia); pWLNEO, pSV2CAT, pOG44, pXT1, pSG (Stratagene); pSVK3, pBPV, pMSG, pSVL (Pharmacia); pQE-30 (QIAexpress).

*Bacteriophage vectors*

The P1 bacteriophage vector may contain large inserts ranging from about 80 to about 100 kb. The construction of P1 bacteriophage vectors such as p158 or p158/neo8 are notably described by Sternberg (1992) Trends Genet. 8:1-16, and Sternberg (1994) Mamm. Genome. 5:397-404, which disclosure is hereby incorporated by reference in its entirety. Recombinant P1 clones comprising GENSET nucleotide sequences may be designed for inserting large polynucleotides of more than 40 kb [see, Linton *et al.*, (1993) J. Clin. Invest. 92:3029-3037], which disclosure is hereby incorporated by reference in its entirety. To generate P1 DNA for transgenic experiments, a preferred protocol is the protocol described by McCormick *et al.*, (1994) Genet. Anal. Tech. Appl. 11:158-164, which disclosure is hereby incorporated by reference in its entirety. Briefly, *E. coli* (preferably strain NS3529) harboring the P1 plasmid are grown overnight in a suitable broth medium containing 25 µg/ml of kanamycin. The P1 DNA is prepared from the *E. coli* by alkaline

lysis using the Qiagen Plasmid Maxi kit (Qiagen, Chatsworth, CA, USA), according to the manufacturer's instructions. The P1 DNA is purified from the bacterial lysate on two Qiagen-tip 500 columns, using the washing and elution buffers contained in the kit. A phenol/chloroform extraction is then performed before precipitating the DNA with 70% ethanol. After solubilizing the DNA in TE (10 mM Tris-HCl, pH 7.4, 1 mM EDTA), the concentration of the DNA is assessed by spectrophotometry.

When the goal is to express a P1 clone comprising GENSET polypeptide-encoding nucleotide sequences in a transgenic animal, typically in transgenic mice, it is desirable to remove vector sequences from the P1 DNA fragment, for example by cleaving the P1 DNA at rare-cutting sites within the P1 polylinker (*SfiI*, *NotI* or *SalI*). The P1 insert is then purified from vector sequences on a pulsed-field agarose gel, using methods similar to those originally reported for the isolation of DNA from YACs [see, e. g., Schedl *et al.*, (1993a), *Nature*, 362: 258-261; Peterson *et al.*, (1993), *Proc. Natl. Acad. Sci. USA*, 90 :7593-7597], which disclosures are hereby incorporated by reference in their entireties. At this stage, the resulting purified insert DNA can be concentrated, if necessary, on a Millipore Ultrafree-MC Filter Unit (Millipore, Bedford, MA, USA – 30,000 molecular weight limit) and then dialyzed against microinjection buffer (10 mM Tris-HCl, pH 7.4; 250  $\mu$ M EDTA) containing 100 mM NaCl, 30  $\mu$ M spermine, 70  $\mu$ M spermidine on a microdialysis membrane (type VS, 0.025  $\mu$ M from Millipore). The intactness of the purified P1 DNA insert is assessed by electrophoresis on 1% agarose (Sea Kem GTG; FMC Bio-products) pulse-field gel and staining with ethidium bromide.

#### *Viral vectors*

In one specific embodiment, the vector is derived from an adenovirus. Preferred adenovirus vectors according to the invention are those described by Feldman and Steg, (1996), *Medecine/Sciences*, 12:47-55, or Ohno *et al.*, (1994) *Science*. 265:781-784, which disclosures are hereby incorporated by reference in their entireties. Another preferred recombinant adenovirus according to this specific embodiment of the present invention is the human adenovirus type 2 or 5 (Ad 2 or Ad 5) or an adenovirus of animal origin (French patent application No. FR-93.05954, which disclosure is hereby incorporated by reference in its entirety). Further included in the present invention are adeno-associated virus vectors.

Retrovirus vectors and adeno-associated virus vectors are generally understood to be the recombinant gene delivery systems of choice for the transfer of exogenous polynucleotides *in vivo*, particularly to mammals, including humans. Particularly preferred retroviruses for the preparation or construction of retroviral *in vitro* or *in vivo* gene delivery vehicles of the present invention include retroviruses selected from the group consisting of Mink-Cell Focus Inducing Virus, Murine Sarcoma Virus, Reticuloendotheliosis virus and Rous Sarcoma virus. Particularly preferred Murine Leukemia Viruses include the 4070A and the 1504A viruses, Abelson (ATCC No VR-999), Friend (ATCC No VR-245), Gross (ATCC No VR-590), Rauscher (ATCC No VR-998) and

Moloney Murine Leukemia Virus (ATCC No VR-190; PCT Application No WO 94/24298). Particularly preferred Rous Sarcoma Viruses include Bryan high titer (ATCC Nos VR-334, VR-657, VR-726, VR-659 and VR-728). Other preferred retroviral vectors are those described in Roth *et al.*, (1996) Nature Medicine, 2(9):985-991, PCT Application No WO 93/25234, PCT

- 5 Application No WO 94/ 06920, Roux *et al.* (1989), Proc. Natl. Acad. Sci. U.S.A. 86:9079-9083, Julan *et al.* (1992), J. Gen. Virol. 73:3251-3255, and Neda *et al.* (1991), J. Biol. Chem. 266:14143-14146, which disclosures are hereby incorporated by reference in their entireties.

#### *BAC vectors*

- The bacterial artificial chromosome (BAC) cloning system [Shizuya *et al.* (1992), Proc. Natl. Acad. Sci. U.S.A. 89:8794-8797], which disclosure is hereby incorporated by reference in its entirety, has been developed to stably maintain large fragments of genomic DNA (100-300 kb) in *E. coli*. A preferred BAC vector comprises a pBeloBAC11 vector that has been described by Kim U-J. *et al.* (1996), Genomics 34:213-218, which disclosure is hereby incorporated by reference in its entirety. BAC libraries are prepared with this vector using size-selected genomic DNA that has
- 15 been partially digested using enzymes that permit ligation into either the *Bam* HI or *Hind*III sites in the vector. Flanking these cloning sites are T7 and SP6 RNA polymerase transcription initiation sites that can be used to generate end probes by either RNA transcription or PCR methods. After the construction of a BAC library in *E. coli*, BAC DNA is purified from the host cell as a supercoiled circle. Converting these circular molecules into a linear form precedes both size
- 20 determination and introduction of the BACs into recipient cells. The cloning site is flanked by two *Not* I sites, permitting cloned segments to be excised from the vector by *Not* I digestion. Alternatively, the DNA insert contained in the pBeloBAC11 vector may be linearized by treatment of the BAC vector with the commercially available enzyme lambda terminase that leads to the cleavage at the unique *cos*N site, but this cleavage method results in a full length BAC clone
- 25 containing both the insert DNA and the BAC sequences.

#### *Baculovirus*

- Another specific suitable host vector system is the pVL1392/1393 baculovirus transfer vector (PharMingen) that is used to transfect the SF9 cell line (ATCC No. CRL 1711) which is derived from *Spodoptera frugiperda*. Other suitable vectors for the expression of the GENSET
- 30 polypeptide of the present invention in a baculovirus expression system include those described by Chai *et al.* (1993), Biotechnol. Appl. Biochem. 18:259-273; Vlasak, *et al.* (1983), Eur. J. Biochem. 135:123-126, and Lenhard *et al.*, (1996) Gene. 169:187-190, which disclosures are hereby incorporated by reference in their entireties.

#### Delivery Of The Recombinant Vectors

- 35 To effect expression of the polynucleotides and polynucleotide constructs of the invention, the constructs must be delivered into a cell. This delivery may be accomplished *in vitro*, as in laboratory procedures for transforming cell lines, or *in vivo* or *ex vivo*, as in the treatment of certain

diseases states.

One mechanism is viral infection where the expression construct is encapsulated in an infectious viral particle. The expression construct, preferably a recombinant viral vector as discussed herein, may transduce packaging cells through any means known in the art such as electroporation, liposomes, and CaPO<sub>4</sub> precipitation. The packaging cell generates infectious viral particles that include a polynucleotide encoding a polypeptide of the present invention. Such viral particles then may be employed to transduce eukaryotic cells *in vitro*, *ex vivo* or *in vivo*. The transduced eukaryotic cells will express a polypeptide of the present invention. Preferably, the viruses used in the present invention are rendered replication deficient by deletion of one or more of all or a portion of the following genes: E1a, E1b, E3, E4, E2a, or L1 through L5 (U.S. Patent 6,228,844, which disclosure is hereby incorporated by reference in its entirety). Viral delivery is discussed in more detail herein (see also, U.S. Patent 5,968,821, which disclosure is hereby incorporated by reference in its entirety).

Retrovirus vectors and adeno-associated virus vectors are generally understood to be the recombinant gene delivery system of choice for the transfer of exogenous genes *in vivo*, particularly into humans. These vectors provide efficient delivery of genes into cells, and the transferred nucleic acids are stably integrated into the chromosomal DNA of the host. A major prerequisite for the use of retroviruses is to ensure the safety of their use, particularly with regard to the possibility of the spread of wild-type virus in the cell population. The development of specialized cell lines (termed "packaging cells") which produce only replication-defective retroviruses has increased the utility of retroviruses for gene therapy, and defective retroviruses are well characterized for use in gene transfer for gene therapy purposes (for a review see Miller, A. D. (1990) Blood 76:271). Thus, recombinant retrovirus can be constructed in which part of the retroviral coding sequence (gag, pol, env) has been replaced by nucleic acid encoding one of the subject CCR-proteins, rendering the retrovirus replication defective. The replication defective retrovirus is then packaged into virions which can be used to infect a target cell through the use of a helper virus by standard techniques.

Protocols for producing recombinant retroviruses and for infecting cells *in vitro* or *in vivo* with such viruses can be found in Current Protocols in Molecular Biology, Ausubel, F. M. et al. (eds.) Greene Publishing Associates, (1989), Sections 9.10-9.14 and other standard laboratory manuals. Examples of suitable retroviruses include pLJ, pZIP, pWE and pEM which are well known to those skilled in the art. Examples of suitable packaging virus lines for preparing both ecotropic and amphotropic retroviral systems include .psi.Crip, .psi.Cre, .psi.2 and .psi.Am. Retroviruses have been used to introduce a variety of genes into many different cell types, including neural cells, epithelial cells, endothelial cells, lymphocytes, myoblasts, hepatocytes, bone marrow cells, *in vitro* and/or *in vivo* (see for example Eglitis, et al. (1985) Science 230:1395-1398; Danos and Mulligan (1988) Proc. Natl. Acad. Sci. USA 85:6460-6464; Wilson, et al. (1988) Proc.

Natl. Acad. Sci. USA 85:3014-3018; Armentano, et al. (1990) Proc. Natl. Acad. Sci. USA 87:6141-6145; Huber, et al. (1991) Proc. Natl. Acad. Sci. USA 88:8039-8043; Ferry, et al. (1991) Proc. Natl. Acad. Sci. USA 88:8377-8381; Chowdhury, et al. (1991) Science 254:1802-1805; van Beusechem, et al. (1992) Proc. Natl. Acad. Sci. USA 89:7640-7644; Kay, et al. (1992) Human Gene Therapy 3:641-647; Dai, et al. (1992) Proc. Natl. Acad. Sci. USA 89:10892-10895; Hwu, et al. (1993) J. Immunol. 150:4104-4115; U.S. Pat. No. 4,868,116; U.S. Pat. No. 4,980,286; PCT Application WO 89/07136; PCT Application WO 89/02468; PCT Application WO 89/05345; and PCT Application WO 92/07573).

Furthermore, it has been shown that it is possible to limit the infection spectrum of retroviruses and consequently of retroviral-based vectors, by modifying the viral packaging proteins on the surface of the viral particle (see, for example PCT publications WO93/25234, WO94/06920, and WO94/11524). For instance, strategies for the modification of the infection spectrum of retroviral vectors include: coupling antibodies specific for cell surface antigens to the viral env protein (Roux, et al. (1989) PNAS 86:9079-9083; Julan, et al. (1992) J. Gen Virol 73:3251-3255; and Goud, et al. (1983) Virology 163:251-254); or coupling cell surface ligands to the viral env proteins (Neda, et al. (1991) J Biol Chem 266:14143-14146). Coupling can be in the form of the chemical cross-linking with a protein or other variety (e.g. lactose to convert the env protein to an asialoglycoprotein), as well as by generating fusion proteins (e.g. single-chain antibody/ env fusion proteins). This technique, while useful to limit or otherwise direct the infection to certain tissue types, and can also be used to convert an ecotropic vector in to an amphotropic vector.

Moreover, use of retroviral gene delivery can be further enhanced by the use of tissue- or cell-specific transcriptional regulatory sequences that control expression of the desired gene.

Another viral gene delivery system useful in the present invention utilizes adenovirus-derived vectors. The genome of an adenovirus can be manipulated such that it encodes a gene product of interest, but is inactivate in terms of its ability to replicate in a normal lytic viral life cycle (see, for example, Berkner, et al. (1988) BioTechniques 6:616; Rosenfeld, et al. (1991) Science 252:431-434; and Rosenfeld, et al. (1992) Cell 68:143-155). Suitable adenoviral vectors derived from the adenovirus strain Ad type 5 dl324 or other strains of adenovirus (e.g., Ad2, Ad3, Ad7 etc.) are well known to those skilled in the art. Recombinant adenoviruses can be advantageous in certain circumstances in that they are not capable of infecting nondividing cells and can be used to infect a wide variety of cell types, including airway epithelium (Rosenfeld, et al. (1992) cited supra), endothelial cells (Lemarchand et al.(1992) Proc. Natl. Sci. USA 89:6482-6486), hepatocytes (Herz and Gerard (1993) Proc. Natl. Acad. Sci. USA 90:2812-2816) and muscle cells (Quantin, et al. (1992) Proc. Natl. Acad. Sci. USA 89:2581-2584). Furthermore, the virus particle is relatively stable and amenable to purification and concentration, and as above, can be modified so as to affect the spectrum of infectivity. Additionally, introduced adenoviral

Yet another viral vector system useful for delivery of polynucleotides is the adeno-associated virus (AAV). Adeno-associated virus is a naturally occurring defective virus that requires another virus, such as an adenovirus or a herpes virus, as a helper virus for efficient replication and a productive life cycle. (For a review see Muzyczka, et al., Curr. Topics in Micro and Immunol. (1992) 158:97-129). It is also one of the few viruses that may integrate its nucleic acids into non-dividing cells, and exhibits a high frequency of stable integration (see for example Flotte *et al.*, (1992) Am. J. Respir. Cell Mol. Biol. 7:349-356; Am. J. Respir. Cell. Mol. Biol. 7:349-356; Samulski et al. (1989) J. Virol. 63:3822-3828; and McLaughlin et al. (1989) J. Virol. 62:1963-1973). Vectors containing as little as 300 base pairs of AAV can be packaged and can integrate. Space for exogenous DNA is limited to about 4.5 kb. An AAV vector such as that described in Tratschin, et al. (1985) Mol. Cell. Biol. 5:3251-3260 can be used to introduce DNA into cells. A variety of nucleic acids have been introduced into different cell types using AAV vectors (see for example Hermonat, et al. (1984) Proc. Natl. Acad. Sci. USA 81:6466-6470; Tratschin, et al. (1985) Mol. Cell. Biol. 4:2072-2081; Wondisford, et al. (1988) Mol. Endocrinol. 2:32-39; Tratschin, et al. (1984) J. Virol. 51:611-619; and Flotte, et al. (1993) J. Biol. Chem. 268:3781-3790).

30 Other viral vector systems that may have application in gene therapy have been derived from herpes virus, vaccinia virus, and several RNA viruses. In particular, herpes virus vectors may provide a unique strategy for persistence of inserted gene expression in cells of the central nervous system and ocular tissue (Pepose, et al. (1994) Invest Ophthalmol Vis Sci 35:2662-2666).

Several non-viral methods for the transfer of polynucleotides into cultured mammalian  
35 cells are also contemplated by the present invention, and include, without being limited to, calcium  
phosphate precipitation [Graham *et al.*, (1973) Virol. 52:456-457; Chen *et al.* (1987) Mol. Cell.  
Biol. 7:2745-2752]; DEAE-dextran [Gopal (1985) Mol. Cell. Biol., 5:1188-1190]; electroporation

[Tur-Kaspa *et al.* (1986) Mol. Cell. Biol. 6:716-718; Potter *et al.*, (1984) Proc. Natl. Acad. Sci. U.S.A. 81(22):7161-7165]; direct microinjection (Harland *et al.*, (1985) J. Cell. Biol. 101:1094-1095); DNA-loaded liposomes [Nicolau *et al.*, (1982) Biochim. Biophys. Acta. 721:185-190; Fraley *et al.*, (1979) Proc. Natl. Acad. Sci. USA. 76:3348-3352]; and receptor-mediated

5 transfection. [Wu and Wu (1987), J. Biol. Chem. 262:4429-4432; and Wu and Wu (1988), Biochemistry 27:887-892], which disclosures are hereby incorporated by reference in their entireties. Some of these techniques may be successfully adapted for *in vivo* or *ex vivo* use, as discussed herein.

Once the expression polynucleotide has been delivered into the cell, it may be stably

10 integrated into the genome of the recipient cell. This integration may be in the cognate location and orientation via homologous recombination (gene replacement) or it may be integrated in a random, non-specific location (gene augmentation). In yet further embodiments, the nucleic acid may be stably maintained in the cell as a separate, episomal segment of DNA. Such nucleic acid segments or "episomes" encode sequences sufficient to permit maintenance and replication

15 independent of or in synchronization with the host cell cycle.

One specific embodiment for a method for delivering a protein or peptide to the interior of a cell of a vertebrate *in vivo* comprises the step of introducing a preparation comprising a physiologically acceptable carrier and a naked polynucleotide operatively coding for the polypeptide of interest into the interstitial space of a tissue comprising the cell, whereby the naked

20 polynucleotide is taken up into the interior of the cell and has a physiological effect. This is particularly applicable for transfer *in vitro* but it may be applied to *in vivo* as well.

Compositions for use *in vitro* and *in vivo* comprising a "naked" polynucleotide are described in PCT application No. WO 90/11092 (Vical Inc.) and also in PCT application No. WO 95/11307 (Institut Pasteur, INSERM, Université d'Ottawa) as well as in the articles of Tascon *et al.* (1996), Nature Medicine. 2(8):888-892 and of Huygen *et al.*, (1996) Nature Medicine.

25 2(8):893-898, which disclosures are hereby incorporated by reference in their entireties.

In still another embodiment of the invention, the transfer of a naked polynucleotide of the invention, including a polynucleotide construct of the invention, into cells may be accomplished with particle bombardment (biolistic), said particles being DNA-coated microprojectiles

30 accelerated to a high velocity allowing them to pierce cell membranes and enter cells without killing them, such as described by Klein *et al.*, (1987) Nature 327:70-73, which disclosure is hereby incorporated by reference in its entirety. Liposomal preparations for use in the present invention include cationic (positively charged), anionic (negatively charged) and neutral preparations. However, cationic liposomes are particularly preferred because a tight charge

35 complex can be formed between the cationic liposome and the polyanionic nucleic acid. Cationic liposomes have been shown to mediate intracellular delivery of plasmid DNA (Felgner, *et al.*, Proc. Nat. Acad. Sci. USA (1987) 84:7413-7416, which is herein incorporated by reference);

mRNA (Malone, et al., Proc. Natl. Acad. Sci. USA (1989) 86:6077-6081, which is herein incorporated by reference); and purified transcription factors (Debs et al., J. Biol. Chem. (1990) 265:10189-10192, which is herein incorporated by reference), in functional form.

Cationic liposomes are readily available. For example, N[1-2,3-dioleoyloxy)propyl]-N,N,N-triethylammonium (DOTMA) liposomes are particularly useful and are available under the trademark Lipofectin, from GIBCO BRL, Grand Island, N.Y. (See, also, Feigner, et al., Proc. Natl. Acad. Sci. USA (1987) 84:7413-7416, which is herein incorporated by reference). Other commercially available liposomes include transfectace (DDAB/DOPE) and DOTAP/DOPE (Boehringer).

Similarly, anionic and neutral liposomes are readily available, such as from Avanti Polar Lipids (Birmingham, Ala.), or can be easily prepared using readily available materials. Such materials include phosphatidyl choline, cholesterol, phosphatidyl ethanolamine, dioleoylphosphatidyl choline (DOPC), dioleoylphosphatidyl glycerol (DOPG), dioleoylphosphatidyl ethanolamine (DOPE), among others. These materials can also be mixed with the DOTMA and DOTAP starting materials in appropriate ratios. Methods for making liposomes using these materials are well known in the art.

For example, commercially dioleoylphosphatidyl choline (DOPC), dioleoylphosphatidyl glycerol (DOPG), and dioleoylphosphatidyl ethanolamine (DOPE) can be used in various combinations to make conventional liposomes, with or without the addition of cholesterol. The liposomes can comprise multilamellar vesicles (MLVs), small unilamellar vesicles (SUVs), or large unilamellar vesicles (LUVs), with SUVs being preferred. The various liposome-nucleic acid complexes are prepared using methods well known in the art (Straubinger, et al., Methods of Immunology (1983), 101:512-527, which is herein incorporated by reference). For example, MLVs containing nucleic acid can be prepared by depositing a thin film of phospholipid on the walls of a glass tube and subsequently hydrating with a solution of the material to be encapsulated (U.S. Patent 5,965,421, which disclosure is hereby incorporated by reference).

Generally, the ratio of DNA to liposomes will be from about 10: 1 to about 1: 10. Preferably, the ratio will be from about 5:1 to about 1:5. More preferably, the ratio will be about 3: 1 to about 1: 3. Still more preferably, the ratio will be about 1: 1. Additionally, liposomes may be targeted to specific cell types by embedding a targeting moiety such as a member of a receptor- receptor ligand pair into the lipid envelope of the vesicle. Useful targeting moieties specifically bind cell surface ligands, for example, CD48 or the SCF receptor on mast cells. Thus, anti-CD48 antibodies or SCF ligand are examples of useful mast cell-targeting moieties (U.S. Patent 6,177,433, U.S. Patent 6,110,490, and P.C.T No. WO97/04748, which disclosures are hereby incorporated by reference in their entireties).

In a further embodiment, the polynucleotide of the invention may be entrapped in a liposome [Ghosh and Bacchawat, (1991), Targeting of liposomes to hepatocytes, IN: Liver

Diseases, Targeted diagnosis and therapy using specific receptors and ligands. Eds., Marcel Dekeker, New York, pp. 87-104; Wong, *et al.* (1980), *Gene*. 10:87-94; Nicolau *et al.*, (1987), *Meth. Enzymol.*, 149:157-76, which disclosures are hereby incorporated by reference in their entireties].

5 In a specific embodiment, the invention provides a composition for the *in vivo* production of the GENSET polypeptides described herein. It comprises a naked polynucleotide operatively coding for this polypeptide, in solution in a physiologically acceptable carrier, and suitable for introduction into a tissue to cause cells of the tissue to express the said protein or polypeptide.

The amount of vector to be injected to the desired host organism varies according to the  
10 site of injection. As an indicative dose, it will be injected between 0.1 and 100 µg of the vector in an animal body, preferably a mammal body, for example a mouse body.

In another embodiment of the vector according to the invention, it may be introduced *in vitro* in a host cell, preferably in a host cell previously harvested from the animal to be treated and more preferably a somatic cell such as a muscle cell. In a subsequent step, the cell that has been  
15 transformed with the vector coding for the desired GENSET polypeptide or the desired fragment thereof is reintroduced into the animal body in order to deliver the recombinant protein within the body either locally or systemically.

#### Secretion vectors

Some of the GENSET cDNAs or genomic DNAs of the invention may also be used to  
20 construct secretion vectors capable of directing the secretion of the proteins encoded by genes inserted in the vectors. Such secretion vectors may facilitate the purification or enrichment of the proteins encoded by genes inserted therein by reducing the number of background proteins from which the desired protein must be purified or enriched. Exemplary secretion vectors are described below.

25 The secretion vectors of the present invention include a promoter capable of directing gene expression in the host cell, tissue, or organism of interest. Such promoters include the Rous Sarcoma Virus promoter, the SV40 promoter, the human cytomegalovirus promoter, and other promoters familiar to those skilled in the art.

A signal sequence from a polynucleotide of the invention and signal sequences of clone  
30 inserts of the deposited clone pool is operably linked to the promoter such that the mRNA transcribed from the promoter will direct the translation of the signal peptide. The host cell, tissue, or organism may be any cell, tissue, or organism which recognizes the signal peptide encoded by the signal sequence in the GENSET cDNA or genomic DNA. Suitable hosts include mammalian cells, tissues or organisms, avian cells, tissues, or organisms, insect cells, tissues or organisms, or  
35 yeast.

In addition, the secretion vector contains cloning sites for inserting genes encoding the proteins which are to be secreted. The cloning sites facilitate the cloning of the insert gene in

frame with the signal sequence such that a fusion protein in which the signal peptide is fused to the protein encoded by the inserted gene is expressed from the mRNA transcribed from the promoter. The signal peptide directs the extracellular secretion of the fusion protein.

The secretion vector may be DNA or RNA and may integrate into the chromosome of the host, be stably maintained as an extrachromosomal replicon in the host, be an artificial chromosome, or be transiently present in the host. Preferably, the secretion vector is maintained in multiple copies in each host cell. As used herein, multiple copies means at least 2, 5, 10, 20, 25, 50 or more than 50 copies per cell. In some embodiments, the multiple copies are maintained extrachromosomally. In other embodiments, the multiple copies result from amplification of a chromosomal sequence.

Many nucleic acid backbones suitable for use as secretion vectors are known to those skilled in the art, including retroviral vectors, SV40 vectors, Bovine Papilloma Virus vectors, yeast integrating plasmids, yeast episomal plasmids, yeast artificial chromosomes, human artificial chromosomes, P element vectors, baculovirus vectors, or bacterial plasmids capable of being transiently introduced into the host.

The secretion vector may also contain a polyA signal such that the polyA signal is located downstream of the gene inserted into the secretion vector.

After the gene encoding the protein for which secretion is desired is inserted into the secretion vector, the secretion vector is introduced into the host cell, tissue, or organism using calcium phosphate precipitation, DEAE-Dextran, electroporation, liposome-mediated transfection, viral particles or as naked DNA. The protein encoded by the inserted gene is then purified or enriched from the supernatant using conventional techniques such as ammonium sulfate precipitation, immunoprecipitation, immunochromatography, size exclusion chromatography, ion exchange chromatography, and hplc. Alternatively, the secreted protein may be in a sufficiently enriched or pure state in the supernatant or growth media of the host to permit it to be used for its intended purpose without further enrichment.

The signal sequences may also be inserted into vectors designed for gene therapy. In such vectors, the signal sequence is operably linked to a promoter such that mRNA transcribed from the promoter encodes the signal peptide. A cloning site is located downstream of the signal sequence such that a gene encoding a protein whose secretion is desired may readily be inserted into the vector and fused to the signal sequence. The vector is introduced into an appropriate host cell. The protein expressed from the promoter is secreted extracellularly, thereby producing a therapeutic effect.

#### Cell Hosts

Another object of the invention comprises a host cell that has been transformed or transfected with one of the polynucleotides described herein, and in particular a polynucleotide either comprising a GENSET polypeptide-encoding polynucleotide regulatory sequence or the polynucleotide coding for a GENSET polypeptide. Also included are host cells that are

transformed (prokaryotic cells), transfected (eukaryotic cells), or transduced with a recombinant vector such as one of those described above. However, the cell hosts of the present invention can comprise any of the polynucleotides of the present invention. Preferred host cells used as recipients for the expression vectors of the invention are the following:

- 5 a) Prokaryotic host cells: *Escherichia coli* strains (I.E.DH5- $\alpha$  strain), *Bacillus subtilis*, *Salmonella typhimurium*, and strains from species like *Pseudomonas*, *Streptomyces* and *Staphylococcus*.
- b) Eukaryotic host cells: HeLa cells (ATCC No.CCL2; No.CCL2.1; No.CCL2.2), Cv 1 cells (ATCC No.CCL70), COS cells (ATCC No.CRL1650; No.CRL1651), Sf-9
- 10 cells (ATCC No.CRL1711), C127 cells (ATCC No. CRL-1804), 3T3 (ATCC No. CRL-6361), CHO (ATCC No. CCL-61), human kidney 293. (ATCC No. 45504; No. CRL-1573) and BHK (ECACC No. 84100501; No. 84111301).

The present invention also encompasses primary, secondary, and immortalized homologously recombinant host cells of vertebrate origin, preferably mammalian origin and

15 particularly human origin, that have been engineered to: a) insert exogenous (heterologous) polynucleotides into the endogenous chromosomal DNA of a targeted gene, b) delete endogenous chromosomal DNA, and/or c) replace endogenous chromosomal DNA with exogenous polynucleotides. Insertions, deletions, and/or replacements of polynucleotide sequences may be to the coding sequences of the targeted gene and/or to regulatory regions, such as promoter and

20 enhancer sequences, operably associated with the targeted gene.

In addition to encompassing host cells containing the vector constructs discussed herein, the invention also encompasses primary, secondary, and immortalized host cells of vertebrate origin, particularly mammalian origin, that have been engineered to delete or replace endogenous genetic material (e.g., coding sequence), and/or to include genetic material (e.g., heterologous

25 polynucleotide sequences) that is operably associated with the polynucleotides of the invention, and which activates, alters, and/or amplifies endogenous polynucleotides. For example, techniques known in the art may be used to operably associate heterologous control regions (e.g., promoter and/or enhancer) and endogenous polynucleotide sequences via homologous recombination, see, e.g., U.S. Patent No. 5,641,670, issued June 24, 1997; International Publication No. WO 96/29411,

30 published September 26, 1996; International Publication No. WO 94/12650, published August 4, 1994; Koller, *et al.*, (1989); and Zijlstra, *et al.* (1989) (the disclosures of each of which are incorporated by reference in their entireties).

The present invention further relates to a method of making a homologously recombinant host cell *in vitro* or *in vivo*, wherein the expression of a targeted gene not normally expressed in the

35 cell is altered. Preferably the alteration causes expression of the targeted gene under normal growth conditions or under conditions suitable for producing the polypeptide encoded by the targeted gene. The method comprises the steps of: (a) transfecting the cell *in vitro* or *in vivo* with

a polynucleotide construct, said polynucleotide construct comprising; (i) a targeting sequence; (ii) a regulatory sequence and/or a coding sequence; and (iii) an unpaired splice donor site, if necessary, thereby producing a transfected cell; and (b) maintaining the transfected cell *in vitro* or *in vivo* under conditions appropriate for homologous recombination.

- 5       The present invention further relates to a method of altering the expression of a targeted gene in a cell *in vitro* or *in vivo* wherein the gene is not normally expressed in the cell, comprising the steps of: (a) transfecting the cell *in vitro* or *in vivo* with a polynucleotide construct, said polynucleotide construct comprising: (i) a targeting sequence; (ii) a regulatory sequence and/or a coding sequence; and (iii) an unpaired splice donor site, if necessary, thereby producing a
- 10   transfected cell; and (b) maintaining the transfected cell *in vitro* or *in vivo* under conditions appropriate for homologous recombination, thereby producing a homologously recombinant cell; and (c) maintaining the homologously recombinant cell *in vitro* or *in vivo* under conditions appropriate for expression of the gene.

- 15       The present invention further relates to a method of making a polypeptide of the present invention by altering the expression of a targeted endogenous gene in a cell *in vitro* or *in vivo* wherein the gene is not normally expressed in the cell, comprising the steps of: a) transfecting the cell *in vitro* with a polynucleotide construct, said polynucleotide construct comprising: (i) a targeting sequence; (ii) a regulatory sequence and/or a coding sequence; and (iii) an unpaired splice donor site, if necessary, thereby producing a transfected cell; (b) maintaining the transfected
- 20   cell *in vitro* or *in vivo* under conditions appropriate for homologous recombination, thereby producing a homologously recombinant cell; and c) maintaining the homologously recombinant cell *in vitro* or *in vivo* under conditions appropriate for expression of the gene thereby making the polypeptide.

- 25       The present invention further relates to a polynucleotide construct which alters the expression of a targeted gene in a cell type in which the gene is not normally expressed. This occurs when the polynucleotide construct is inserted into the chromosomal DNA of the target cell, wherein said polynucleotide construct comprises: a) a targeting sequence; b) a regulatory sequence and/or coding sequence; and c) an unpaired splice-donor site, if necessary. Further included are a polynucleotide construct, as described above, wherein said polynucleotide construct further
- 30   comprises a polynucleotide which encodes a polypeptide and is in-frame with the targeted endogenous gene after homologous recombination with chromosomal DNA.

- 35       The compositions may be produced, and methods performed, by techniques known in the art, such as those described in U.S. Patent NOs: 6,054,288; 6,048,729; 6,048,724; 6,048,524; 5,994,127; 5,968,502; 5,965,125; 5,869,239; 5,817,789; 5,783,385; 5,733,761; 5,641,670; 5,580,734; International Publication NOs: WO96/29411, WO 94/12650; and scientific articles described by Koller, *et al.*, (1994). (The disclosures of each of which are incorporated by reference in their entireties.)

GENSET gene expression in mammalian cells, preferably human cells, may be rendered defective, or alternatively may be altered by replacing endogenous GENSET polypeptide-encoding genes in the genome of an animal cell by a GENSET polypeptide-encoding polynucleotide according to the invention. These genetic alterations may be generated by homologous

5 recombination using previously described specific polynucleotide constructs.

Mammal zygotes, such as murine zygotes may be used as cell hosts. For example, murine zygotes may undergo microinjection with a purified DNA molecule of interest.

Any one of the polynucleotides of the invention, including the Polynucleotide constructs described herein, may be introduced in an embryonic stem (ES) cell line, preferably a mouse ES  
10 cell line. ES cell lines are derived from pluripotent, uncommitted cells of the inner cell mass of pre-implantation blastocysts. Preferred ES cell lines are the following: ES-E14TG2a (ATCC No.CRL-1821), ES-D3 (ATCC No.CRL1934 and No. CRL-11632), YS001 (ATCC No. CRL-11776), 36.5 (ATCC No. CRL-11116). ES cells are maintained in an uncommitted state by culture in the presence of growth-inhibited feeder cells which provide the appropriate signals to preserve  
15 this embryonic phenotype and serve as a matrix for ES cell adherence. Preferred feeder cells are primary embryonic fibroblasts that are established from tissue of day 13- day 14 embryos of virtually any mouse strain, that are maintained in culture, such as described by Abbondanzo *et al.*, (1993), Meth. Enzymol., Academic Press, New York, pp 803-823 and are growth-inhibited by irradiation, such as described by Robertson, (1987), Embryo-derived stem cell lines; In: E.J.  
20 Robertson Ed. Teratocarcinomas and embrionic stem cells: a practical approach. IRL Press, Oxford, pp. 71, or by the presence of an inhibitory concentration of LIF, such as described by Pease and William, (1990), Exp. Cell. Res. 190: 209-211, which disclosures are hereby incorporated by reference in their entireties.

The constructs in the host cells can be used in a conventional manner to produce the gene  
25 product encoded by the recombinant sequence.

#### Transgenic Animals

The terms "transgenic animals" or "host animals" are used herein to designate animals that have their genome genetically and artificially manipulated so as to include one of the nucleic acids according to the invention. The cells affected may be somatic, germ cells, or both. Preferred  
30 animals are non-human mammals and include those belonging to a genus selected from *Mus* (e.g. mice), *Rattus* (e.g. rats) and *Oryctogalus* (e.g. rabbits) which have their genome artificially and genetically altered by the insertion of a nucleic acid according to the invention. In one embodiment, the invention encompasses non-human host mammals and animals comprising a recombinant vector of the invention or a GENSET gene disrupted by homologous recombination  
35 with a knock out vector.

The transgenic animals of the invention all include within a plurality of their cells a cloned recombinant or synthetic DNA sequence, more specifically one of the purified or isolated nucleic

acids comprising a GENSET polypeptide coding sequence, a GENSET polynucleotide regulatory sequence, a polynucleotide construct, or a DNA sequence encoding an antisense polynucleotide such as described in the present specification.

Generally, a transgenic animal according to the present invention comprises any of the  
5 polynucleotides, the recombinant vectors and the cell hosts described in the present invention. In a first preferred embodiment, these transgenic animals may be good experimental models in order to study the diverse pathologies related to the dysregulation of the expression of a given GENSET gene, in particular the transgenic animals containing within their genome one or several copies of an inserted polynucleotide encoding a native GENSET polypeptide, or alternatively a mutant  
10 GENSET polypeptide.

In a second preferred embodiment, these transgenic animals may express a desired polypeptide of interest under the control of the regulatory polynucleotides of the GENSET gene, leading to high yields in the synthesis of this protein of interest, and eventually to tissue specific expression of the protein of interest.

15 The design of the transgenic animals of the invention may be made according to the conventional techniques well known from the one skilled in the art. For more details regarding the production of transgenic animals, and specifically transgenic mice, it may be referred to US Patents Nos 4,873,191, issued Oct. 10, 1989; 5,464,764 issued Nov 7, 1995; and 5,789,215, issued Aug 4, 1998; these documents being herein incorporated by reference to disclose methods  
20 producing transgenic mice.

Transgenic animals of the present invention are produced by the application of procedures which result in an animal with a genome that has incorporated exogenous genetic material. The procedure involves obtaining the genetic material which encodes either a GENSET polypeptide coding sequence, a GENSET polynucleotide regulatory sequence, or a DNA sequence encoding a  
25 GENSET polynucleotide antisense sequence, or a portion thereof, such as described in the present specification. A recombinant polynucleotide of the invention is inserted into an embryonic or ES stem cell line. [See, e.g., Thomas, *et al.* (1987) Cell. 51:503-512, which disclosure is hereby incorporated by reference in its entirety.] An illustrative positive-negative selection procedure that may be used according to the invention is described by Mansour *et al.*, (1988) Nature. 336:348-  
30 352, which disclosure is hereby incorporated by reference in its entirety.

The positive cells are then isolated, cloned and injected into 3.5 days old blastocysts from mice, such as described by Bradley (1987) [Production and analysis of chimaeric mice *In*: E.J. Robertson (Ed.), Teratocarcinomas and embryonic stem cells: A practical approach. IRL Press, Oxford, pp.113)], which disclosure is hereby incorporated by reference in its entirety. The  
35 blastocysts are then inserted into a female host animal and allowed to grow to term. Alternatively, the positive ES cells are brought into contact with embryos at the 2.5 days old 8-16 cell stage (morulae) such as described by Wood, *et al.* (1993), Proc. Natl. Acad. Sci. USA, 90: 4582-4585, or

by Nagy *et al.*, (1993), Proc. Natl. Acad. Sci. USA 90: 8424-8428, which disclosures are hereby incorporated by reference in their entireties, the ES cells being internalized to colonize extensively the blastocyst including the cells which will give rise to the germ line.

The offspring of the female host are tested to determine which animals are transgenic e.g.  
5 include the inserted exogenous DNA sequence and which ones are wild type.

Thus, the present invention also concerns a transgenic animal containing a nucleic acid, a recombinant expression vector or a recombinant host cell according to the invention.

In another embodiment, transgenic animals are produced by microinjecting polynucleotides into a fertilized oocyte. Methods for culturing fertilized  
10 oocytes to the pre-implantation stage are described, e.g., by Gordon, et al. [(1984) Methods in Enzymology, 101, 414]; Hogan, et al. [(1986) in Manipulating the mouse embryo, A Laboratory Manual. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y (for the mouse embryo)]; Hammer, et al. [(1985) Nature, 315, 680 (for rabbit and porcine embryos)]; Gandolfi, et al. [(1987) J. Reprod. Fert. 81, 23-28]; Rexroad, et al. [(1988) J. Anim. Sci. 66, 947-953] (for ovine  
15 embryos)]; and Eyestone, et al. [(1989) J. Reprod. Fert. 85, 715-720]; Camous et al. [(1984) J. Reprod. Fert. 72, 779-785]; and Heyman, et al. [(1987) Theriogenology 27, 5968 (for bovine embryos)]; the disclosures of each of which are incorporated herein in their entireties. Pre-implantation embryos are then transferred to an appropriate female by standard methods to permit the birth of a transgenic or chimeric animal, depending upon the stage of development when the  
20 transgene is introduced.

Any of a number of methods known in the art can be used to detect the presence of a transgene in a pre-implantation embryo.

In a particularly preferred embodiment of the present invention, transgenic mammals are generated that secrete recombinant GENSET polypeptides in their milk. As the mammary gland is  
25 a highly efficient protein-producing organ, such methods can be used to produce protein concentrations in the gram per liter range, and often significantly more. Preferably, expression in the mammary gland is accomplished by operably linking the polynucleotide encoding the GENSET polypeptide to a mammary gland specific promoter and, optionally, other regulatory elements. Suitable promoters and other elements include, but are not limited to, those derived  
30 from mammalian short and long WAP, alpha, beta, and kappa, casein, alpha and beta lactoglobulin, beta-CN 5' genes, as well as the the mouse mammary tumor virus (MMTV) promoter. Such promoters and other elements may be derived from any mammal, including, but not limited to, cows, goats, sheep, pigs, mice, rabbits, and guinea pigs. Promoter and other regulatory sequences, vectors, and other relevant teachings are provided, e.g., by Clark (1998) J  
35 Mammary Gland Biol Neoplasia 3:337-50; Jost, et al. (1999) Nat. Biotechnol 17:160-4; U.S. Patent Nos. 5,994,616; 6,140,552; 6,013,857; Sohn, et al. (1999) DNA Cell Biol. 18:845-52; Kim, et al. (1999) J. Biochem. (Japan) 126:320-5; Soulier, et al. (1999) Euro. J. Biochem. 260:533-9;

Zhang, et al. (1997) Chin. J. Biotech. 13:271-6; Rijnkels, et al. (1998) Transgen. Res. 7:5-14; Korhonen, et al. (1997) Euro. J. Biochem. 245:482-9; Uusi-Oukari, et al. (1997) Transgen. Res. 6:75-84; Hitchin, et al. (1996) Prot. Expr. Purif. 7:247-52; Platenburg, et al. (1994) Transgen. Res. 3:99-108; Heng-Cherl, et al. (1993) Animal Biotech. 4:89-107; and Christa, et al. (2000) Euro. J. Biochem. 267:1665-71; the entire disclosure of each of which is herein incorporated by reference.

In another embodiment, the polypeptides of the invention can be produced in milk by introducing polynucleotides encoding the polypeptides into somatic cells of the mammary gland in vivo, e.g. mammary secreting epithelial cells. For example, plasmid DNA can be infused through the nipple canal, e.g. in association with DEAE-dextran (see, e.g., Hens, et al. (2000) Biochim. Biophys. Acta 1523:161-171), in association with a ligand that can lead to receptor-mediated endocytosis of the construct (see, e.g., Sobolev, et al. (1998) 273:7928-33), or in a viral vector such as a retroviral vector, e.g. the Gibbon ape leukemia virus (see, e.g., Archer, et al. (1994) PNAS 91:6840-6844). In any of these embodiments, the polynucleotide may be operably linked to a mammary gland specific promoter, as described above, or, alternatively, any strongly expressing promoter such as CMV or MoMLV LTR.

The suitability of any vector, promoter, regulatory element, etc. for use in the present invention can be assessed beforehand by transfecting cells such as mammary epithelial cells, e.g. MacT cells (bovine mammary epithelial cells) or GME cells (goat mammary epithelial cells), in vitro and assessing the efficiency of transfection and expression of the transgene in the cells.

In a preferred embodiment, a retroviral vector such as as Gibbon ape leukemia viral vector is used, as described in Archer, et al. ((1994) PNAS 91:6840-6844). As retroviral infection typically requires cell division, cell division in the mammary glands can be stimulated in conjunction with the administration of the vector, e.g. using a factor such as estradiol benzoate, progesterone, reserpine, or dexamethasone. Further, retroviral and other methods of infection can be facilitated using accessory compounds such as polybrene. Alternatively, an adenoviral or adeno-associated viral vector may be used to infect non-dividing cells as discussed herein.

In any of the herein-described methods for obtaining GENSET polypeptides from milk, the quantity of milk obtained, and thus the quantity of GENSET polypeptides produced, can be enhanced using any standard method of lactation induction, e.g. using hexestrol, estrogen, and/or progesterone.

The polynucleotides used in such embodiments can either encode a full-length GENSET protein or a GENSET fragment. Typically, the encoded polypeptide will include a signal sequence to ensure the secretion of the protein into the milk.

Recombinant Cell Lines Derived From The Transgenic Animals Of The Invention:

A further object of the invention comprises recombinant host cells obtained from a transgenic animal described herein. In one embodiment the invention encompasses cells derived from non-human host mammals and animals comprising a recombinant vector of the invention or a

GENSET gene disrupted by homologous recombination with a knock out vector.

Recombinant cell lines may be established *in vitro* from cells obtained from any tissue of a transgenic animal according to the invention, for example by transfection of primary cell cultures with vectors expressing *onc*-genes such as SV40 large T antigen, as described by Chou, (1989),

- 5 Mol. Endocrinol. 3: 1511-1514, and Shay *et al.*, (1991), Biochem. Biophys. Acta, 1072: 1-7, which disclosures are hereby incorporated by reference in their entireties.

#### USES OF POLYPEPTIDES OF THE INVENTION

##### **Protein of SEQ ID NO:24 (Internal designation Clone 47-14-1-C3-CL0\_5)**

The cDNA of clone 47-14-1-C3-CL0\_5 (SEQ ID NO:23) encodes the protein of SEQ ID

- 10 NO:24, comprising the amino acid sequence:

MVPFIYLQAHFTLCSGWSSTYRDLRKG VYVPYTQGWEGELGTDLV SIPHGPNVTVRANI

CALFMLPLCLMVCQWRCLRLRQQHDDFADDISLLK. Accordingly, it will be appreciated

that all characteristics and uses of polypeptides of SEQ ID NO:24 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 47-14-

- 20 1-C3-CL0\_5. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:23 described throughout the present application also pertain to the nucleic acids included in Clone 47-14-1-C3-CL0\_5. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:23, SEQ ID NO:24, and Clone 47-14-1-C3-CL0\_5. Also preferred are polypeptide fragments having a biological activity as described herein  
25 and the polynucleotides encoding the fragments.

Further preferred are compositions comprising the amino acid sequence:

DRARKRIGFAVSACH. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:24 encodes amyloid processing inhibitor protein (APIP). APIP is expressed in mammalian tissues, particularly in neuronal cells, and is an incomplete aspartyl  
5 protease which is able to bind substrate but lacks catalytic activity. Examples of compounds which interact with APIP include, but are not limited to, amyloid beta precursor protein, amyloid precursor like protein-1, amyloid precursor like protein-2, Protease nexin-2, Anti-trypsin protein, Kunitz protease inhibitors and amyloid like proteins.

Amyloid beta precursor protein (APP) can be processed by several types of proteases to  
10 yield fragments that are soluble or insoluble (Nunan and Small, FEBS Lett (2000) 483(1):6-10, which disclosures are hereby incorporated by reference in their entirety). Sequential cleavage of APP by beta secretase and gamma secretase yields a secreted and insoluble fibrillar amyloid protein, known as beta amyloid, which is the major component of extracellular amyloid plaques. Deposition of beta amyloid proteins form intraneuronal neurofibrillary tangles, amyloid plaques  
15 and vascular amyloid deposits characteristic of both Alzheimer's Disease and aged Down's Syndrome. Defects in processing APP can also lead to cerebral hemorrhage. Polypeptides of SEQ ID NO:24 and fragments thereof, bind to APP and other amyloid like proteins, and reduce the rate of processing of these proteins.

In a number of embodiments, APIP is used to bind to and/or inhibit any of a number of  
20 substrates in a biological sample. For example, one preferred embodiment is directed to a method of contacting compositions comprising APIP with APP. Further preferred is a method of contacting compositions comprising APIP with amyloid precursor like protein-1 (APLP1). Still further preferred is a method of contacting compositions comprising APIP with amyloid precursor like protein-2 (APLP2). Such methods are useful, e.g. to inhibit the activity of the substrate such  
25 as APP, APLP1, or APLP2, or to label the substrate, e.g. by labeling APIP and using it to specifically bind to and thus allow the visualization of the substrate or a cell or tissue expressing the substrate.

Another embodiment is directed at a method for reducing catabolism of extracellular secreted amyloid beta precursor protein (APP) which comprises contacting a mammalian cell with  
30 APIP. Preferably the said mammalian cell produces APP. The mammalian cell is preferably a neuronal cell. The mammal is preferably a rodent, canine, or primate.

Another embodiment is directed at a method for reducing catabolism of extracellular secreted APLP1 which comprises contacting a mammalian cell with APIP. Preferably the said mammalian cell produces APLP1. The mammalian cell is preferably a neuronal cell. The  
35 mammal is preferably a rodent, canine, or primate.

Another embodiment is directed at a method for reducing catabolism of extracellular secreted APLP2 which comprises contacting a mammalian cell with APIP. Preferably the said

mammalian cell produces APLP2. The mammalian cell is preferably a neuronal cell. The mammal is preferably a rodent, canine, or primate.

Amyloid plaques in the brain contribute to disruption of neuronal conductivity which leads to disturbances in behavior, perception, memory and mood. Another preferred embodiment of the invention is directed to a method of preventing or alleviate mood disorders by contacting compositions comprising APIP neuronal cells. Further preferred is a method to prevent or alleviate schizophrenia by contacting compositions comprising APIP with neuronal cells. Still further preferred is a method to prevent or alleviate Alzheimer's disease by contacting compositions comprising APIP with neuronal cells.

Amyloidosis also occurs in the pancreas and may contribute to the development of glucose intolerance, insulin insufficiency, or diabetes. A preferred embodiment is directed to a method of preventing or alleviating glucose intolerance by contacting compositions comprising APIP with pancreatic cells. Further preferred is a method to prevent or alleviate insulin insufficiency by contacting compositions comprising APIP with pancreatic cells. Still further preferred is a method to prevent or alleviate diabetes by contacting compositions comprising APIP with pancreatic cells.

It should be appreciated that preferred compositions of the invention to be used in methods of the invention described for clone 47-14-1-C3-CL0\_5 of SEQ ID NO:23 include polypeptides of SEQ ID NO:24 (APIP), and fragments thereof, and compositions comprising the polypeptides of SEQ ID NO:24, and fragments thereof.

**20 Protein of SEQ ID NO:28 (Internal designation Clone 117401\_106-006-4-0-B11-F)**

The cDNA of clone 117401\_106-006-4-0-B11-F (SEQ ID NO:27) encodes the protein of SEQ ID NO:28. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:28 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 117401\_106-006-4-0-B11-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:27 described throughout the present application also pertain to the nucleic acids included in Clone 117401\_106-006-4-0-B11-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments. The gene for the protein of SEQ ID NO:28 is located on chromosome 8.

The protein of SEQ ID NO:28 is referred to herein as Frangiopogen. Frangiopogen is highly expressed in human fetal liver and lung. It stimulates liver regeneration, has mitogenic activity and is actively involved in embryonic development. Frangiopogen is involved in complex regulatory processes including cell proliferation and angiogenesis.

In a preferred embodiment of the invention, Frangiopogen is used in tissue treatment compositions to promote wound healing, preferably after injury, such as ischemia, or after surgery, including general surgery, ear-, nose- and throat surgery, tissue transplantation, dermal or dental or artificial joint transplants, or plastic surgery. Further preferred are uses for Frangiopogen in tissue

treatment compositions for tissue regeneration.

Preferred tissue treatment compositions of the present invention include physiologically acceptable formulations comprising the protein of SEQ ID NO:28. Further preferred are physiologically acceptable formulations comprising the protein of SEQ ID NO:28 in combination  
5 with an additional compound such as any or all of the compounds selected from the group consisting of fibrin, fibrinogen, thrombin, factor XIII, calcium chloride, a plasminogen activator, a plasmin inhibitor (such as aprotin), a growth factor, and a polysaccharide such as hyaluronic acid. Still further preferred are formulations comprising the protein of SEQ ID NO:28 alone or in compositions, e.g. as described in US Patents 6,083,902 and 5,631,011, herein incorporated by  
10 reference in their entirety.

In further embodiments, the tissue treatment compositions of the invention are used in methods of treating injuries comprising the step of contacting a wound or injured tissue with a healing or regenerative effective amount (an amount that would increase the rate or progression of healing or regeneration as compared to the same wound or injured tissue not treated with a  
15 composition of the present invention) of a Frangiopogen polypeptide. Further embodiments include use of the tissue treatment compositions of the invention for topical application to a site of injury (e.g. as defined as a site in which the integument is damaged in such a way as to expose the dermis), following an accident or following surgery comprising the step of contacting the injured tissue with a healing or regenerative effective amount of a Frangiopogen polypeptide. In still  
20 further embodiments, the tissue treatment compositions of the invention, alone or in combination with chondrocytes such as embryonic chondrocytes, are used in methods to treat joint cartilage and bone defect repair.

The present invention provides for methods of stimulating proliferation of endothelial cells comprising the step of contacting endothelial cells with a proliferative effective amount of a  
25 Frangiopogen polypeptide of the present invention. Preferably the endothelial cells are vascular endothelial cells, arterial or venous. Further preferably, the method results in angiogenesis or the process of vascularization of a tissue involving the development of new capillary blood vessels. Preferably, angiogenesis occurs in a mammal, more preferably the mammal is a dog, cat, horse, cow, pig or human.

In addition, the present invention provides for an antibody that specifically binds a Frangiopogen polypeptide of the present invention. The antibody may be monoclonal or polyclonal. The invention also provides for a method of inhibiting the growth of endothelial cells comprising the step of contacting a biological sample comprising endothelial cells with a growth  
30 inhibiting effective amount of an anti-Frangiopogen antibody. Preferably, the endothelial cells are vascular endothelial cells, arterial or venous. Further preferably, the methods results in the inhibition of angiogenesis or blood vessel growth. Further preferably, the inhibition of angiogenesis occurs in a mammal, more preferably the mammal is a dog, cat, horse, cow, pig or

human.

Alternatively, the invention provides for a Frangiopogen polypeptide-cytotoxic agent conjugate, whereby the cytotoxic agent is covalently or noncovalently, recombinantly or nonrecombinantly, attached or conjugated to a Frangiopogen polypeptide using cytotoxic agents and methods well known in the art. The invention also provides for a method of inhibiting the growth of endothelial cells comprising the step of contacting a biological sample comprising endothelial cells or an individual with a growth inhibiting or endothelial cell killing effective amount of a Frangiopogen-cytotoxic agent conjugate. Preferably, the endothelial cells are vascular endothelial cells. Further preferably, the methods results in the inhibition of angiogenesis or blood vessel growth. Further preferably, the inhibition of angiogenesis occurs in a mammal, more preferably the mammal is a dog, cat, horse, cow, pig or human. To examine whether a particular anti-Frangiopogen antibody or a Frangiopogen-cytotoxic agent conjugate is useful to disrupt vascular growth or angiogenesis, models well known in the art may be used, e.g., the chick chorioallantoic membrane assay.

Preferred polypeptides for use in the methods of the present invention include the polypeptides of SEQ ID NO:28 comprising the amino acid sequence:

25 characteristics and uses of the polynucleotides of SEQ ID NOs:9, 11, 13, and 15 and polypeptides  
of SEQ ID NOs:10, 12, 14, and 16 described throughout the present application also pertain to the  
human cDNAs of Clones 147103\_106-024-1-0-H6-F, 224168\_116-096-3-0-G11-F, 243303\_116-  
118-4-0-A3-F, and 225432\_116-083-3-0-C6-F, and the polypeptides encoded thereby. Preferred  
compositions of the invention include polynucleotides and polypeptides of Clones 147103\_106-  
30 024-1-0-H6-F, 224168\_116-096-3-0-G11-F, 243303\_116-118-4-0-A3-F, and 225432\_116-083-3-  
0-C6-F; SEQ ID NOs:9, 11, 13, and 15; SEQ ID NOs:10, 12, 14, and 16. Also preferred are  
polypeptide fragments having a biological activity as described herein and the polynucleotides  
encoding the fragments.

- sLRP10 is a non-membrane, soluble member of the Low Density Lipoprotein Receptor  
35 (LDLR) family. This family is characterized by the presence of a number of conserved, cysteine-  
rich LDLR domains. This domain folds to form a defined ligand-binding structure. Most  
members of the LDLR family are transmembrane proteins that function in clathrin-mediated

endocytosis of various ligands. These ligands are usually then destroyed by lysosomal degradation. However, shorter, secreted family members have been described (U.S. Patent 5,496,926 and Quinn, K. et al., Exp. Cell Res. 251: 433-41(1999) which disclosures are hereby incorporated by reference in their entirety). The LDLR family of proteins is capable of binding a variety of protein and lipoprotein ligands. Furthermore, certain viruses target the LDLR domain to gain entry to cells expressing LDLR family members. LDLR proteins are expressed on a variety of cell types including hepatocytes, neurons, fibroblasts, epithelial, adipose, muscle, and pancreatic cells.

High levels of Low Density Lipoprotein (LDL), Very Low Density Lipoprotein (VLDL), chylomicrons, and Apolipoprotein E (ApoE) are associated with atherosclerosis and other cholesterol-associated disorders. These molecules are subjects of intense study in the medical field. As a preferred embodiment, sLRP10 is used to bind LDL, VLDL, chylomicrons, and ApoE. While many members of the LDLR family, such as LDLR and alpha-2-macroglobulin receptor, are very large (>400 kD) membrane spanning proteins, sLRP10 is relatively small and not membrane associated. Thus, sLRP10 is an easily purified polypeptide that can be used for binding LDLR domain ligands. As a part of this embodiment, sLRP10 polypeptide is covalently or non-covalently attached to a solid matrix and allowed to bind LDL, VLDL, chylomicrons, or ApoE in solution using techniques well known in the art. Once bound, these proteins can be purified using the following steps: i) wash the solid matrix to get rid of contaminants, ii) elute the protein of interest using more stringent conditions, e.g., increasing salt concentration.

Additional aspects of this embodiment include methods of detecting and quantifying LDL, VLDL, chylomicrons, or ApoE bound to sLRP10 using techniques common in the art (e.g., Western blotting, ELISA, or use of a labeled secondary detection method) comprising the steps of obtaining a biological sample suspected of containing LDL, VLDL, chylomicrons, or ApoE; contacting said sample with an LDL, VLDL, chylomicrons, or ApoE binding sLRP10 polypeptide of the present invention under conditions suitable for binding of sLRP10 to LDL, VLDL, or ApoE; detecting the presence or absence of LDL, VLDL, or ApoE by detecting the presence or absence of sLRP10 bound to LDL, VLDL, or ApoE. This embodiment is useful, for example, as a diagnostic tool for detecting plasma levels of these proteins.

In another embodiment of the invention, the sLRP10 polypeptide is used to bind LDL, VLDL, chylomicrons, and ApoE in vivo and remove these molecules from the bloodstream. In this embodiment, the sLRP10 polypeptide may further be expressed as a fusion protein with a polypeptide signal specifying excretion from the body. The invention is delivered to individuals at risk of atherosclerosis or arterial lipoprotein deposits of LDL, VLDL, chylomicrons, or ApoE as determined by common medical techniques including those described in U.S. Patent 5,652,224, incorporated herein by reference in its entirety, and comprising the steps of i) determining the familial predisposition of the individual for these disorders, ii) obtaining a biological sample from

the individual, and iii) subjecting that sample to analysis for lipoprotein content. Delivery includes administering an appropriate amount of sLRP10 polypeptide to the bloodstream of the diagnosed individual, e.g., by injection.

ApoE is also associated with the pathogenesis of diabetes. Abnormally high levels of ApoE are linked to amyloid plaques and destruction of pancreatic P-cells. Furthermore, ApoE has antioxidant activity (Miyata and Smith, *Nature Genet.* 14: 55-61 (1996) which disclosures are hereby incorporated by reference in their entirety) and oxidative damage destroys P-cells in type 1 diabetes (Bach J., *Endocrin. Rev.* 15: 516-542 (1994) and PCT application WO9846743, incorporated herein by reference in its entirety). This embodiment of the invention could further be delivered to patients suffering from or at risk of diabetes to reduce levels of pancreatic ApoE. In this embodiment, the sLRP10 polypeptide may further be expressed as a fusion protein with a polypeptide signal specifying excretion from the body. An appropriate dosage of sLRP10 may be delivered specifically to the bloodstream, by injection for example, or to pancreatic cells using methods known in the art including those described in U.S. Patent 5,652,224, incorporated herein by reference in its entirety. These include steps comprising i) construction of a recombinant viral vector comprising the DNA of, or corresponding to, a portion of the genome of an adenovirus, which portion is capable of infecting a pancreatic cell, operatively linked to the nucleotide sequence of the invention and the regulatory sequences directing its expression; ii) delivery of an effective amount of the recombinant adenoviral vector to an individual at risk for diabetes.

The polypeptide sLRP10 invention can bind ApoE as well as the amyloid precursor protein (APP), both of which are associated with the pathogenesis of Alzheimer's disease (Kounnas, M.Z., et al., *Cell* 82:331-40 (1995) which disclosures are hereby incorporated by reference in their entirety). As a further embodiment of the invention, sLRP10 polypeptide is used to bind these proteins in neuronal cell populations to allow study of Alzheimer's pathogenesis. In particular, the invention is directly added to a population of neurons to block ApoE activity and study the formation of amyloid plaques.

sLRP10 is also able to bind the protooncogene Wnt-1 (Tamai, K., et al., *Nature* 407:530-35 (2000) which disclosures are hereby incorporated by reference in their entirety). Wnt-1 usually functions as a soluble growth factor that binds to Frizzled receptors but Wnt-1 has also been associated with transformation of cells (van Ooyen, A., *Cell* 39:233-40 (1984) which disclosures are hereby incorporated by reference in their entirety). Additionally, Wnt-1 has been associated with schizophrenia (Shackleford, G., et al., *Neuron* 11:865-75 (1993) which disclosures are hereby incorporated by reference in their entirety), making this protein of particular interest to the biomedical community. Another embodiment of the sLRP10 polypeptide invention provides a method to study Wnt-1 and its effects using techniques common to the art. This embodiment provides a method of purifying Wnt-1 protein from a biological solution using steps comprising: i) attaching sLRP10 to a solid matrix; ii) applying a solution containing Wnt-1; iii) allowing Wnt-1

to bind to sLRP10; iv) washing and eluting Wnt-1. Purifying Wnt-1 is useful for a number of applications, for example to use purified Wnt-1 as a growth factor to administer to cells, to generate antibodies against Wnt-1, and others. Additionally, this embodiment of the sLRP10 polypeptide is used to bind Wnt-1 in solution and prevent its association with Frizzled receptors, thereby preventing molecular signaling events leading to cell growth, proliferation, and/or transformation.

sLRP10 binds to viruses comprising the Rous sarcoma, Flaviviridae (including hepatitis C), and Rhinovirus (including those responsible for the "common cold") families (Bates, P., et al., Cell 93:1043-51 (1993), Agnello, V., et al., PNAS 96:12766-71 (1999), Hofer, F., et al., PNAS 91:1839-42 (1994) which disclosures are hereby incorporated by reference in their entirety). As a preferred embodiment of the invention, the sLRP10 polypeptide is used to bind viruses in solution. This embodiment can be used to detect and quantify virus by techniques common to the art (e.g., fluorescent labeling of sLRP10) comprising steps of obtaining a biological sample suspected of containing virus from at least one of the Rous sarcoma, Flaviviridae, or Rhinovirus families; contacting said sample with labeled or otherwise detectable sLRP10 polypeptide; and detecting and quantifying virus by visualizing the labeled sLRP10.

Membrane spanning LDLR family members are targeted by viruses of the Rous sarcoma, Flaviviridae, and Rhinovirus families for entry into cells. However, as sLRP10 is not associated with the cellular membrane, it acts to block viral binding to LDLR proteins on the cells that express these receptors, thereby preventing infection of those cells. As a preferred embodiment of the invention, the sLRP10 protein is used to bind virus and prevent infection of LDLR family-expressing cells using methods known in the art including U.S. Patent 5,496,926, incorporated herein by reference in its entirety. This embodiment may be carried out by steps comprising: i) adding the sLRP10 polypeptide directly to cells, e.g. cells that express an LDLR family receptor, that may be exposed to a viral sample and ii) preventing the infection of said cells by viruses of the Rous sarcoma, Flaviviridae, and Rhinovirus families.

**Protein of SEQ ID NO:20 (Internal designation Clone 158523\_106-030-2-0-A3-F)**

The cDNA of Clone 158523\_106-030-2-0-A3-F (SEQ ID NO:19) encodes the OsteoAngioRemodeling (OAR) protein comprising the amino acid sequence

MRAWIFFLLCLAGRALAAPQQEALPDETEVVEETVAEVTEVSVGANPVQVEVGEFDDGA  
EETEEVVAAENPCQNHCKHGKVCELDENNTPMCVCQDPTSCPAIGFEKVCSDNKNKTF  
DSSCHFFATKCTLEGTKKGHKLHLDYIGPCKYIPCLDSELTEFPLRMRDWLKNVLVTLYE  
RDEDNNLLTEKQKLRVKKIHENEKRLEAGDHPVELLARDCAVSARKAKIKSEM (SEQ ID  
NO:20). Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of  
SEQ ID NO:20 described throughout the present application also pertain to the polypeptides  
encoded by the nucleic acids included in Clone 158523\_106-030-2-0-A3-F. In addition, it will be  
appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:19 described

throughout the present application also pertain to the nucleic acids included in Clone 158523\_106-030-2-0-A3-F. A preferred embodiment of the invention is directed toward the compositions comprising SEQ ID NO:19, SEQ ID NO:20, or Clone 158523\_106-030-2-0-A3-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments. Another preferred embodiment of the invention is directed toward compositions comprising polypeptide fragments of at least six amino acids within SEQ ID NO:20: LLARDCQAVSARK, including those having a biological activity described herein, and the corresponding polynucleotides. Preferred polypeptides of the present invention include polypeptide fragments of SEQ ID NO:20 comprising

- 10 KKIHENEKRL EAGDHPVELLARD CQAVSARKAKIKSEM and the corresponding polynucleotides. Further preferred polypeptides of the present invention include polypeptide fragments of SEQ ID NO:20 comprising  
 DYIGPCKYIPPCLDSELTEFPLMRDWLKNVLVTLYERDEDNNLLTEKQKLRVKKIHENE  
 KRLEAGDHPVELLARD CQAVSARKAKIKSEM and the corresponding polynucleotides.
- 15 Polypeptide fragments of SEQ ID NO:20 having a biological activity of those described herein and polynucleotides encoding the same are also included in the invention. Biological activities include increasing bone density when contacted with osteoblasts, tissue remodeling, and wound healing.

The polypeptides of the OsteoAngioRemodeling (OAR) protein of SEQ ID NO:20 encode a carboxy-terminal variant of the human Osteonectin (also SPARC/ BM-40) protein. OAR is encoded by the polynucleotides of SEQ ID NO:19 and represents an alternative splice variant of the full-length Osteonectin cDNA. This splice variant is characterized by the presence of an alternative carboxy-terminal 15 amino acids starting at residue 219 of the 303-amino acid Osteonectin protein.

- OAR, like Osteonectin, is a non-collagenous, extracellular matrix-associated protein.
- 25 Expression is found in a number of cell types that include osteoblasts, platelets, and vascular epithelia, and is upregulated in sites of proliferation and extracellular matrix (ECM) remodeling. OAR is a modular protein whose domains mediate structure and protein-protein interactions. OAR lacks domain IV of full-length Osteonectin, which contains one of two EF-hand motifs. OAR binds molecules such as collagen, PDGF, and FGF. Collagen type binding specificity is in part determined by differential N-glycosylation of amino acids 71 and 99. This level of regulation is tissue-specific, so that OAR from the bone binds collagens I, III, and V, yolk sac-derived OAR binds only III and V, and platelet-derived OAR does not bind collagen at all. Furthermore, binding decreases in low pH conditions. OAR plays a role in regulating cell mobility, proliferation, bone and tissue remodeling, and metalloproteinase production. OAR is involved in osteoporosis,
- 35 osteoarthritis, atherosclerosis, angiogenesis, obesity, and metastatic tumors.

OAR is associated with increased bone density and remodeling. OAR is also associated with metalloproteinase production, which is vital for bone remodeling. As a preferred

embodiment, the OAR polypeptide of the invention is used to increase the activity of osteoblasts using methods common to the art, for example, by adding a osteoblast-stimulating amount of OAR to increase bone production to a culture of osteoblastic cells. This embodiment is applied to increase the productivity of osteoblasts for purposes comprising study or replacement therapy. As

5 a further embodiment, OAR is used in methods of bone remodeling such as those described in Gerber, H., et al. (1999) Nat. Med. 5:623-8, which disclosures are hereby incorporated by reference in their entirety. For example, OAR is used in a method to promote osteoblast differentiation and bone remodeling by inducing metalloproteinase or osteocalcin production by contacting OAR with osteoblastic cells in culture. Furthermore, OAR is used in a method to

10 promote in vivo osteoblast differentiation by contacting OAR with an area of potential bone growth, for instance, in the growth plate of the femur or in the hip which is often the site of fracture. An effective amount of OAR is delivered to the site by injection or other methods common to the art and effectiveness determined using any suitable method such as X-rays, or methods described in Delany, A., et al. (2000) J. Clin. Invest. 105: 915-23, which disclosure is

15 hereby incorporated by reference in its entirety.

Cells derived from certain tissues adhere to specific collagens. OAR binds collagen types I, III, and V which are found, for example, in epithelia and bone tissue. This allows OAR to act as an anti-adhesion factor by inhibiting normal interaction of collagen in the ECM to cell surface adhesion molecules. This activity is associated with cell migration and differentiation.

20 Furthermore, OAR is associated with increased metalloproteinase expression, which leads to ECM degradation and tissue remodeling. Thus, a preferred embodiment of the invention is directed to a method of using OAR in tissue remodeling, whereby contacting OAR with osteoblasts to inhibit binding of collagen to cells allows tissue remodeling. Further preferred is a method to use OAR in wound healing (e.g., from surgical damage or chronic conditions such as diabetic ulcers), tissue

25 grafts, necrotic or hypoxic tissue in ECM environments comprising collagen types I, III, and V that bind OAR. A method to treat these conditions includes steps comprising: i) identifying the ECM of the tissue in need of repair as one that binds OAR using methods common in the art (e.g., applying fluorescently-labeled OAR to an ECM sample and visualizing by microscopy);

ii) localizing an effective amount of OAR to the wound area either directly or by injection;

30 iii) allowing ECM remodeling to occur as OAR inhibits cell adhesion.

Osteonectin binds to VEGF, which regulates blood vessel formation. This interaction prevents VEGF binding to its receptor. The OAR polypeptide lacks a VEGF-binding domain while it retains its ability to bind the ECM and affect remodeling (Kupprion, C., et al. (1998) J. Biol. Chem. 273:29635-40 which disclosure is hereby incorporated by reference in its entirety). In

35 a preferred embodiment of the invention, OAR polypeptide is used to replace Osteonectin in conditions that require VEGF activity in addition to the ECM interactions that mediate wound healing and tissue remodeling. This is accomplished in steps comprising: i) obtaining a cell or

tissue sample in culture that contains at least VEGF and VEGF-responsive cells; ii) adding OAR to the culture in an amount effective for ECM binding, iii) allowing OAR to enable ECM remodeling as well as VEGF signaling to aid in angiogenesis and tissue healing. In addition, expression of Osteonectin may be inhibited by introducing IL-1 to the affected area and as described in

- 5 Nakamura, S., et al. (1996) *Arthritis Rheum.* 39:539-51, which disclosure is hereby incorporated by reference in its entirety. As a further embodiment, the invention is applied to the growth and healing of necrotic or hypoxic tissue, tissue grafts, and bone-associated tissue. The OAR polypeptide is delivered to these tissues using methods common to the art such as injection or use of OAR polypeptide fused to a targeting molecule specific for the tissue of interest.
- 10 In the extreme, decreased "contact inhibition" from the ECM to the cell surface is linked to tumor formation and metastasis. As OAR inhibits contact of cells to specific types of collagen in the ECM, OAR is involved in metastasis of a number of tumor cell types including breast and prostate carcinomas. In a preferred embodiment of the invention, the OAR polypeptide is used to develop inhibitors of its collagen-binding activity to prevent ECM invasion. This invasion
- 15 includes the proliferation of cells into inappropriate tissues, such as that observed in rheumatoid arthritis and cancers including breast and prostate carcinomas. Inhibitors of OAR are comprised of antibodies raised against the carboxy-terminal 15 amino acids of the OAR polypeptide and small molecules that interfere with OAR collagen binding activity. OAR binding to ECM environments is determined using methods common to the art such as applying fluorescently-labeled OAR to a
- 20 tissue sample and visualizing by microscopy. Effectiveness of OAR inhibitors is determined using the aforementioned method or by observing cell invasion of the ECM as described by Kato, Y., et al. (1998-99) *Invasion Metastasis* 18:105-147, which disclosure is hereby incorporated by reference in its entirety. An example use of this embodiment would include methods comprising the steps: i) purifying the OAR inhibitor such as an antibody using methods common in the art
- 25 (e.g.- affinity chromatography); ii) determining a site of inappropriate ECM invasion using methods common to the art such as tissue imaging, X-ray, or palpation; iii) localizing an effective amount of OAR inhibitor to the site to allow cell surface-collagen interactions and prevent ECM invasion. Localization of the OAR inhibitor is effected using methods common in the art such as injection. Further included in the invention is a method for delivering the OAR polypeptide fused
- 30 to a targeting molecule specific for the tissue of interest.
- OAR binds to growth factors including PDGF, which can induce cell migration and proliferation, and inhibits binding of the growth factor to its receptor under certain conditions. As a preferred embodiment of the invention, the OAR polypeptide is used to inhibit signaling through growth factor receptors such as the PDGF receptor. This embodiment is useful in preventing inappropriate
- 35 growth of PDGF-responsive cells, such as dermal fibroblasts (e.g., in the case of hypertrophic scars) and platelets (e.g., in cases of malignant lymphomas). This embodiment is carried out, for instance to reduce the volume of a hypertrophic scar, by identifying a region with excess scar

tissue using methods described by Nedelec, B., et al. (2000) J. Burn Care Rehabil. 21:205-12, which disclosure is hereby incorporated by reference in its entirety; administering an effective amount of OAR to the scar directly or by injection; and monitoring the scar using aforementioned method or others common to the art.

**5 Protein of SEQ ID NO:30 (Internal designation Clone 133431\_105-092-4-0-G11-F)**

The cDNA of clone 133431\_105-092-4-0-G11-F (SEQ ID NO:29) encodes a variant of the ALEX-1 protein with the amino acid sequence

MGRTREAGCVAAGVVIGAGACYCVYRLAWGRDENEKIWDEDEESTDTSXIGVETVKGA  
KTNAGAGSGAKLQGDSEVKPEVSLGLEDCPGVKEKAHSGSHSGGGLEAKAKALFNTLKE

TRAPATTWPVRRGKFNFYPYKIDDILSAPDLQKVLNILERTNDPFIQEVALVTLGNNAAYSF  
NQNAIRELGGVPIIAKKKKK (SEQ ID NO:30). It will be appreciated that all characteristics and

uses of polypeptides of SEQ ID NO:30 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 133431\_105-092-4-0-G11-F. In

15 addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:29 described throughout the present application also pertain to the nucleic acids included in Clone 133431\_105-092-4-0-G11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:29, SEQ ID NO:30, and Clone 133431\_105-092-4-0-G11-F.

Also preferred are polypeptide fragments having a biological activity as described herein and the

20 polynucleotides encoding the fragments. The gene of SEQ ID NO:29 is located on the X-chromosome. It encodes a new armadillo repeat protein with a death effector domain and is involved in cell-cell adhesion, cell signaling and apoptotic processes and is hereby referred to as Armapoptin.

Armapoptin promotes cell growth and differentiation during embryonic development. It is  
25 part of multi-protein complexes, which mediate cell-cell adhesion, anchorage to the actin cytoskeleton with adjacent cells, and a signal in response to cell adhesion to initiate cell polarity and the formation of epithelia. Armapoptin complexes, which include E-cadherin and different cadherin-binding proteins including  $\beta$ -catenin can also be associated with a tumor suppressor protein such as Adenomatous Polyposis Coli (APC), which is mutated in hereditary colon cancer.  
30 Cell-cell adhesion in normal differentiation processes and malignant proliferation is mediated by the armadillo domain serving as a scaffold for the assembly of multi-protein complexes.

The N-terminal region of Armapoptin contains a death effector domain (DED) comprising residues RLAWGRDENEKIWDEDEES. Death effector domains are involved in caspase-dependent apoptotic processes. Armapoptin is expressed in most tissues, but is not expressed or  
35 significantly underexpressed in breast carcinoma biopsies of patients as well as in epithelial based-tumor cell lines including ovarian carcinoma, cervix adenocarcinoma cells, lung carcinomas, and immortalized endothelial cell lines such as t-HUE2.

- In an embodiment, Armapoptin polynucleotides are used in a method of gene therapies to restore cell-cell adhesion and to promote caspase-dependent apoptosis, preferably in epithelial cell-based tumors including breast carcinoma, ovarian carcinoma, lung carcinoma, non-small cell lung carcinoma (NSCLC), and squamous cell carcinoma of head and neck (SCCHN). Preferred
- 5 compositions of Armapoptin to be used in methods of gene therapy, further referred to as "gene therapy compositions of Armapoptin" are compositions comprising the full-length DNA, SEQ ID NO:29, or fragments thereof, encoding a polypeptide or fragments thereof, including the sequences

- Further preferred are compositions comprising PCR-based subcloning of the gene therapy compositions of Armapoptin into plasmid vectors such as pCMV $\beta$  or pSV $\beta$ , tissue-specific
- 10 promoter-containing plasmids such as the MUC1 promoter, which allows epithelial cell specific expression and is up-regulated during malignancy, and the P450arom promoter II for breast carcinomas employing liposomal delivery systems by methods described in Patel, US Patent 6,225,090, 2001, Thierry, US Patent 6,110,490, 2000; Wolff, et al., US Patent 6,228,844, 2001, Graham, et al., Int.J.Cancer 92:382-387, 2001, Zhou, et al, Cancer Res. 61:2328-2334, 2001, which
- 15 disclosures are hereby incorporated in their entireties. Further preferred are compositions comprising polynucleotides of the invention cloned into adenoviral vectors (Beach, et al., US Patents 5,968,821, 1999, and 6,211,334, 2001; Mehtali, et al., US Patent 6,204,060, 2001), and MoMLV-based retroviral vectors for gene delivery into dividing cells, i.e. tumor tissues according to methods described by Holt, et al., US Patent 6,177,410, 2001, which disclosures are hereby
- 20 incorporated in their entirety.

- Methods to deliver preferred compositions of Armapoptin polynucleotides and fragments thereof, comprise local injection of preferred compositions of the invention into tumor tissue or surrounding vessels, or ex vivo therapy. Further methods comprise tumor tissue specific targeting of Armapoptin polynucleotides or fragments thereof in a plasmid via antibodies or other ligands,
- 25 which recognize tumor-specific receptors. These ligands will be covalently linked to polycations such as poly-L-lysine or liposomes, and complexed with preferred gene therapy compositions of Armapoptin. Preferred tumor cell types to be used in methods of gene therapy include breast carcinoma, cervix adenocarcinoma, ovarian carcinoma, lung carcinoma, and squamous cell carcinoma of head and neck derived from mammalian cells including rodent and human.
- 30 Assessment of therapeutic efficacies will include tumor regression following delivery of preferred gene therapy compositions of Armapoptin as monitored by measurement of tumor circumference. Apoptosis will be measured by morphological assessments including retraction of cytoplasmic extension, cell rounding and detachment, and via MTT assays, which measure mitochondrial function for viability, cell death and caspase activity, and DNA fragmentation analysis as described
- 35 by Noteborn, et al. US Patent 5,981,502, 1999; Boone, et al., J.Biol.Chem. 275:37596-37603, 2000; Shibata, et al., Cancer Gene Therapy. 8:23-35, 2001; Lacour, et al., Cancer Research 61:1645-1651, 2001), which disclosures are hereby incorporated by reference in their entireties.

Further embodiments include putative death effector domains for therapeutic use in caspase-dependent cell death including incubation of carcinoma cells with compositions comprising polypeptides of preferred sequences comprising RLAWGRDENEKIWEDEES and FADD DED-related domains as described in Eberstadt, et al., Nature.392:941-945, 1998, and

5 Hackam, et al., J.Biol.Chem.275:41299-41308, 2000, which disclosures are hereby incorporated by reference in their entirety, with the consensus sequence

SSYRVLLLLISEELDSEELEVLFLCNDIPKRKLEIKTALDLFSALEEQGLLEDNLSLLAE  
LLYRLRLDLLRRLFG.

Further, these DED domain-encoding sequences will be subcloned into expression vectors

10 and used for cell transfections and apoptosis studies as described above.

In another embodiment, Armapoptin polypeptides or fragments thereof will be used as immunotherapeutics by covalent or noncovalent linkage to a cell-specific (e.g. tumor cell-specific) antibody, or to a ligand which is recognized by a tumor cell-specific receptor and internalized. Receptors which are abundantly expressed on tumor cells but not on intact, quiescent tissues to be

15 employed in the present invention include H11 [(C-antigen); Dan, et al., US Patent 6,207,153, 2001], tyrosine growth factor receptors including erbB-2 (HER-2-neu) (Suzuki, et al., Biochim Biophys Acta.1525:191-196, 2001; Kumar, et al., Semin Oncol.27:84-91, 2000; Lango, et al., Current Opin Oncol.13:168-175, 2001), the folate receptor (Ward, Current Opin Mol Ther.2:182-187, 2000), human epidermal growth factor receptor (Schlessinger, et al., US Patent 6,217,866,

20 2001), and endoglin on endothelial cells for tumor vascular targeting (Seon, US Patent 6,200,566, 2001), which disclosures are hereby incorporated by reference in their entirety.

The death effector domain causes neuronal cell death in Huntington's disease (Hackam, et al., J.Biol.Chem. 275:41299-41308, 2000, which disclosures are hereby incorporated by reference in their entirety) by stronger association with the mutant, glutamine rich protein, which causes the

25 disease as opposed to wild-type huntingtin in healthy individuals. Another embodiment uses Armapoptin and ALEX-1, partial sequences thereof including the death effector domain RLAWGRDENEKIWEDEES, and the death effector domain of the huntingtin-interacting protein (HIP-1), conserved among related sequences with the consensus peptide

SSYRVLLLLISEELDSEELEVLFLCNDIPKRKLEIKTALDLFSALEEQGLLEDNLSLLAE

30 LLYRLRLDLLRRLFG for competitive binding studies with wild-type huntingtin and the disease-causing mutant. By contacting polypeptides of the invention with wt- and mt- (glutamine-rich) huntingtin, peptide-protein interactions will be analyzed by biophysical methods and validated using the following steps as described in Scalley, et al., Biochemistry. 38:15927-15935, 1999; Chaillan-Huntington et al., J Biol Chem. 275:5874-5879, 2000; Lohner et al., Biochim

35 Biophys Acta.1462:141-156, 1999; Eberstadt, et al., Nature 392:941-945, 1998, which disclosures are hereby incorporated in their entirety.

Structural transitions in the denatured state ensemble, fluorescence energy transfer, and

determination of peptide conformation and structural characteristics using circular dichroism  
Isothermal titration calorimetry, fluorescence binding assays, and differential scanning calorimetry  
to determine comparative  $K_d$  values, and strength of interactions.

Structure determination of polypeptide/huntingtin complexes by NMR and X-ray

- 5 crystallography. Co-incubation of cell lines like 293 T cells with protein-peptide complexes, and  
co-transfection of cells with wt- and mt-huntingtin- encoding plasmids and cloned oligonucleotides  
for cytotoxicity assays as well known in the art.

Another embodiment includes the method to use armadillo repeats of armapoptin, including  
NFPYKIDDILSAPDLQKVLNILERTNDPFIQEVALVTLGNNAA, and

- 10 YSFNQNAIRELGGVPPIAKLIKTKDPIIREKTYNALNNLSV as single repeats, and naturally  
occurring tandem array repeats  
NFPYKIDDILSAPDLQKVLNILERTNDPFIQEVALVTLGNNAAYSFNQNAIRELGGVPPIAKL  
IKTKDPIIREKTYNALNNLSV for the restoration of cell-cell adhesion in treatment or prevention  
of cancer or other diseases or disorders where restoration of cell-cell adhesion is sought, wherein  
15 said method includes contacting cells in need of cell-cell adhesion with either monomers or  
concatamerized forms, either recombinantly or nonrecombinantly, such as dimmers, trimers, or  
longer repeats, in a cell-cell adhesion restorative amount of an Armapoptin polypeptide of the  
present invention.

**Protein of SEQ ID NO:26 (Internal designation Clone 545542\_182-1-2-0-D12-F)**

- 20 The cDNA of clone 545542\_182-1-2-0-D12-F (SEQ ID NO:25) encodes the 251 amino acid  
human Fibroblast Growth Factor-22 protein (FGF-22) comprising the amino acid sequence:  
MLGARLRLWVCALCSVCSMSVLRAYPNASPLLGSWGGLIHLTYTATARNSYHLQIHKNG  
HVDGAPHQTIYSALMIRSEDAGFVVITGVMSRRYLCMDFRGNIFGSHYFDPENCRFQHQT  
LENGYDVYHSPQYHFLVSLGRAKRAFLPGMNPPYPYSQFLSRRNEIPLIHFNTPIPRRHTRSA  
25 EDDSERDPLNVLKPRARMTAPASCSQELPSAEDNSPMASDPLGVVRGGRVNTHAGGTGP  
EGCRPFAKFI (SEQ ID NO:26). Accordingly, it will be appreciated that all characteristics and  
uses of the polypeptides of SEQ ID NO:26 described throughout the present application also  
pertain to the polypeptides encoded by the nucleic acids included in Clone 545542\_182-1-2-0-  
D12-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of  
30 SEQ ID NO:25 described throughout the present application also pertain to the nucleic acids  
included in Clone 545542\_182-1-2-0-D12-F. A preferred embodiment of the invention is directed  
toward the compositions of SEQ ID NO:25, SEQ ID NO:26, and Clone 545542\_182-1-2-0-D12-F.  
Also preferred are polypeptide fragments having a biological activity as described herein and the  
polynucleotides encoding the fragments.
- 35 FGFs exert their biological effects through interaction with cognate single transmembrane,  
heparin-binding, fibroblast growth factor receptors (FGFR) with intrinsic kinase activity,  
designated fibroblast growth factor receptor 1 (FGFR-1), fibroblast growth factor receptor 2

(FGFR-2), fibroblast growth factor receptor 3 (FGFR-3) and fibroblast growth factor receptor 4 (FGFR-4). Physiologically, FGFs bind heparin sulfate proteoglycans which are sulfated glycosaminoglycans covalently bound to core protein. The ability to bind heparin-like moieties includes FGFs within the more encompassing Heparin Binding Growth Factor (HBGF)

- 5 superfamily of peptide growth factors. Additionally, FGFs bind the cysteine-rich FGF-R (CFR), an integral single transmembrane protein in a mutually exclusive manner with respect to the other FGFRs.

FGF-22 exhibits a pattern of temporal and spatial expression in the embryonic and adult organism most pronounced in the brain, including but not limited to the ventrolateral thalamic  
10 nucleus and thalamus. FGF-22 is directly associated with the inherited disorder Autosomal Dominant Hypophosphatemic Rickets (ADHR), represented by missense mutations in FGF-22 polypeptide residues ARG176GLN and ARG179TRP of SEQ ID 26, respectively, resulting from FGF-22 nucleotide transitions at position G527A and C535T, respectively of SEQ ID 25.

Included as an embodiment of the present invention is a method of elevating serum  
15 phosphate levels to within physiologically acceptable concentrations comprising the step of contacting kidney tissue or cells, in vitro or in vivo, with an effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22  
20 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the kidney cells are nephron renal tubules and associated vascular components (collectively designated the glomerular capsule) capable of altering tubular reabsorption, and/or distal or collecting tubules. Preferably, the kidney  
25 tissue or cell is contacted by administering a FGF-22 polypeptide to an individual. As used herein, the term "individual" includes members of the animal kingdom including but not limited to human beings. Preferably, the FGF-22 polypeptide is administered parenterally, more preferably intraperitoneal.

Further included in the present invention is a method of attenuating osteomalacia or tumor-  
30 induced osteomalacia comprising contacting osseous tissue (osteocytes, osteoblasts, osteoclasts) with an osteomalacia inhibiting effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a  
35 physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue or cell is contacted by

administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, more preferably intraperitoneal.

In another embodiment of the present invention is a method of attenuating osteopenia comprising contacting osseous tissue (osteocytes, osteoblasts, osteoclasts) with an osteopenia  
5 inhibiting effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptably  
10 acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, more preferably intraperitoneal.

In another embodiment of the present invention is a method of attenuating osseous bone  
15 matrix deposition, including defects associated with congenital malformations, osteogenesis imperfecta (types I-IV), osteoporosis (type I and/or type II), rickets, fracture remodeling, surgical repair and restoration, and associated with deficiencies in osteoid mineralization or deposition, comprising contacting osseous tissue (osteocytes, osteoblasts, osteoclasts) with a osteoid  
20 deposition or osteoid mineralization stimulating effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptably acceptable carrier or excipient. Such a carrier  
25 includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, more preferably intraperitoneal.

In another embodiment of the present invention is a method of attenuating bone resorption or jaw atrophy associated with dental abscess (periapical or periodontal) formation or progression,  
30 congenital or derived edentulous conditions, or consequent to elective dental extraction, comprising contacting oral cavity osseous tissue (osteocytes, osteoblasts, osteoclasts) of the mandible or maxilla, preferably located adjacent to the sulcular groove region, with an effective amount of an FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically  
35 acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptably acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water,

glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, by any convenient manner, typically by syringe or catheter at the location of targeted osteosynthesis.

- 5 In a further embodiment of this invention is a method of facilitating osseointegration of dental implant prostheses comprising contacting oral cavity osseous tissue (osteocytes, osteoblasts, osteoclasts) of the maxilla and/or mandible as well as osseous tissue i.e. autogeneic or allogeneic bone graft, or dental biomaterial matrix i.e. coral or hydroxyapatite, incorporated within the dental implant device, or bioabsorbable cement in peri-implant region with an effective amount of an
- 10 FGF-22 polypeptide. Following tooth extraction, implant osteotomies were prepared and FGF-22 polypeptide included with a bioabsorbable cement placed circumferentially within the osteotomies. Implant prostheses were placed into the prepared sites including the FGF-22 dental cement (Meraw et al., (J Periodontol 71: 8-13, 2000)). Preferably, the osseous tissue is contacted by administering a FGF-22 polypeptide to an individual. The polypeptide of the present invention may be employed
- 15 in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the
- 20 FGF-22 polypeptide is administered parenterally, by any convenient manner, typically by syringe or catheter at the location of targeted osteosynthesis. FGF-22 polypeptide is alternatively or additionally administered directly associated with the biodegradable matrix of the dental implant using methods of Illi (US Patent 6,214,008/PCT WO98/46289), Gayer and Comfort (US Patent 6,214,049), and/or associated with the bioabsorbable cement using the methods of Meraw, et al. (J
- 25 Periodontol 71: 8-13, 2000), which disclosures are hereby incorporated by reference in their entireties.

A further embodiment of the current invention is a method of facilitating osteosynthesis of bone to attenuate acetabular erosion or osteonecrosis of the femoral head in advance of orthopedic osseointegration of hip joint implant prostheses for hip arthroplasty comprising contacting implant

- 30 localized osseous tissue (osteocytes, osteoblasts, osteoclasts) of the hip joint, preferably the acetabular region and/or femoral head, with a stimulating effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22
- 35 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue is contacted by

administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, preferably intraperitoneal, or by any convenient manner, or by syringe or catheter at the location of targeted osteosynthesis. FGF-22 polypeptide is additionally administered by incorporation with the biodegradable matrix of the prosthetic joint implant.

- 5       An additional embodiment of this invention is a method of facilitating osteosynthesis of bone to attenuate articular surface erosion or osteonecrosis of the femur and/or tibia and/or patella in advance of orthopedic osseointegration of knee joint implant prostheses for knee joint arthroplasty, or osteochondral fracture repair, or the placement of orthopedic pins or screws, comprising contacting implant localized osseous tissue (osteocytes, osteoblasts, osteoclasts) of the
- 10 knee joint, preferably the articular surfaces, with a stimulating effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not
- 15 limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the osseous tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, preferably intraperitoneal, or by any convenient manner, typically by syringe or catheter at the location of targeted osteosynthesis. FGF-22 polypeptide is additionally
- 20 administered by incorporation with the biodegradable matrix of the prosthetic joint implant. FGF-22 is a potent inducer of epithelial cell proliferation. Therefore, another embodiment of this invention is a method of stimulating epithelial cell proliferation or increasing epithelial cell viability by contacting said cells, in vitro or in vivo, with a proliferative stimulating or viability increasing effective amount of a FGF-22 polypeptide. More specifically a method of promoting
- 25 wound repair or tissue healing, such as resultant from burn, ulcer (e.g., venous ulcers in diabetics), aging, post-operative damage, disease, or other insult, by stimulating epithelial cell proliferation or increasing epithelial cell viability by contacting said cells or tissue, in vitro or in vivo, with a proliferation stimulating or viability increasing effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable
- 30 physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the epithelial tissue is contacted by
- 35 administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, preferably intraperitoneal, or by any convenient manner, typically by syringe or catheter directly at the location of targeted epithelial proliferation.

FGF-22 is a potent regulator of connective tissue proliferation, including embryonic mesenchymal cells, fibroblastic cells of areolar, collagenous and elastic connective tissue, chondrocytes of cartilage and osteocytes of bone. Therefore, another embodiment of this invention is a method of stimulating fibroblast cell proliferation or increasing fibroblast cell viability by

5 contacting said cells, in vitro or in vivo, with a proliferative stimulating or viability increasing effective amount of a FGF-22 polypeptide. A further specified embodiment of the present invention is a method of promoting wound repair or tissue healing, in vitro and in vivo, such as resultant from burn, ulcer, aging, post-operative damage such as tendon and ligament repair (Chan, et al., *Acta Orthop Scand* 71: 513-518, 2000; Kuroda, et al., *Knee Surg Sports Traumatol Arthrosc*

10 8: 120-126, 2000), disease, or other insult, by stimulating connective tissue cell proliferation or increasing connective tissue cell viability by contacting said cells, in vitro or in vivo, with a proliferation stimulating or viability increasing effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for

15 administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptably acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably the cells are located in tendons, ligaments, and synovial membranes. More specifically the cells would be

20 fibroblasts present in loose, dense, collagenous and elastic connective tissues of the tendons and/or ligaments and/or synoviocytes within synovial membranes and contacted using the methods of Chan, et al. (*Acta Orthop Scand* 71: 513-518, 2000) and Kuroda, et al. (*Knee Surg Sports Traumatol Arthrosc* 8: 120-126, 2000), which disclosures are hereby incorporated by reference in their entirety. More preferably the fibroblasts would be induced to actively synthesize dense

25 connective tissue and/or collagen. Preferably, the connective tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, more preferably intraperitoneal.

A further specified embodiment of the present invention is a method of promoting cartilage (hyaline cartilage, fibrocartilage, elastic cartilage) wound repair or tissue healing, in vitro and in

30 vivo, such as resultant from aging, post-operative damage, disease, or other insult, by stimulating cartilage tissue cell proliferation or increasing cartilage tissue cell viability by contacting said cells, in vitro or in vivo, with a proliferation stimulating or viability increasing effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable

35 composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and

combinations thereof. The formulation should suit the mode of administration. Preferably the cells are located within joints and/or articular surfaces involved in interstitial/endogenous growth and/or appositional/exogenous growth, ends of long bones (articular cartilage), ends of ribs (costal cartilage), intervertebral disks, symphysis of pubis, menisci of knee, nasal septum, larynx, pharynx, trachea, bronchi, epiglottis, sternum, Eustachian tubes, and of the external (pinna), middle, and inner ear. More specifically the cells would be ground substance (collagenous or elastic fibers, glycosaminoglycans, chondroitin sulfate matrix) remodeling cells (chondrocytes, chondroblasts, chondroclasts) present in cartilagenous connective tissues and contacted using the methods of Toolan, et al. (J Biomed Mater Res 31: 273-280, 1996), Shida, et al. (J Orthop Res 14: 265-272, 1996), and/or Chan, et al. (Clin Orthop 342: 239-247, 1997), which disclosures are hereby incorporated by reference in their entirety. More preferably the cartilage cells (chondrocytes, chondroblasts) would be induced to actively synthesize ground substance. Preferably, the connective tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally, preferably intraperitoneal, or by any convenient manner, or by syringe or catheter at the location of targeted cartilage connective tissue biosynthesis (Chan et al., Clin Orthop 342: 239-247, 1997).

A further specified embodiment of the present invention is a method of promoting osseous (compact bone, spongy bone) wound repair or tissue healing, in vitro and in vivo, such as resultant from aging, post-operative damage, disease, or other insult, by stimulating osseous connective tissue cell (osteoblast progenitor stromal stem cell, osteocyte, osteoblast, osteoclast) proliferation or increasing osseous connective tissue cell viability by contacting said cells, in vitro or in vivo, with a proliferation stimulating or viability increasing effective amount of a FGF-22 polypeptide. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably the cells (osteoblast progenitor stromal stem cell, osteocytes, osteoblast) would be induced to actively synthesize intestinal matrix substance containing mineral salts such as calcium phosphate and calcium carbonate as well as collagenous fibers. The osseous tissue cells would be contacted using the methods of Mathijssen, et al. (J Craniofac Genet Dev Biol 20: 127-136, 2000), Reiff, et al. (J Trauma 50: 433-438, 2001) and/or Mackenzie, et al. (Plast Reconstr Surg 107: 989-996, 2001). In response to FGF-22 treatment, radiomorphometric (percentage of radiopacity of defect) and histomorphometric (square millimeters of new bone formation) methods would be used to derive quantitative outcome data. Preferably, the osseous connective tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the FGF-22 polypeptide is administered parenterally,

preferably intraperitoneal, or by any convenient manner, or by syringe or catheter at the location of targeted osteosynthesis (Radomsky, et al., Clin Orthop 355 Suppl: S283-S293, 1998), or by directed intraosseous injection using the methods of (Nakamura, et al., J Orthop Res 15: 307-313, 1996; Nakamura et al., Int Orthop 22: 49-54, 1998).

- 5 FGF-22 is expressed in the ventrolateral thalamic nucleus of the CNS, a region associated with paralysis agitans, or Parkinson's Disease. Surgical intervention using thalamotomy for Parkinson's disease involves introduction of lesions in the ventrolateral thalamus to relieve tremor and improve rigidity. Therefore, a further embodiment of this invention is a method of attenuating Parkinson's Disease associated tremors, or unrelated benign essential tremors, by contacting
- 10 ventrolateral thalamic tissue comprising the steps of contacting said cells with an effective amount of a FGF-22 polypeptide. Another aspect of the present invention relates to a method for enhancing and/or stimulating and/or maintaining and/or regenerating the formation and/or survival of neurons in vitro or in the central nervous system of a mammal which comprises contacting neurons or neural progenitor cells, e.g., in vitro or by administering to said mammal, an effective
- 15 amount of FGF-22 for a time and under conditions sufficient to effect an increase in and/or to maintain the number of neurons in the central nervous system. Preferably the cells and/or tissue is located within the thalamic region of the CNS. More preferably the cells and/or tissue are of the thalamic ventral nuclei. The polypeptide of the present invention may be employed in combination with a suitable physiologically acceptable carrier to comprise a physiologically acceptable
- 20 composition for administration. Such compositions comprise a therapeutically effective amount of the FGF-22 polypeptide and a physiologically acceptably acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The formulation should suit the mode of administration. Preferably, the CNS tissue is contacted by administering a FGF-22 polypeptide to an individual. Preferably, the
- 25 FGF-22 polypeptide is administered parenterally, with the route of administration intraperitoneal, intramuscular, or by intravenous injection, or using gene therapy, although additional routes are possible such as infusion, drip, intracerebral injection (Mufson, et al., Prog Neurobiol 57: 451-484, 1999) and/or implants (Shults, et al., Brain Res 883: 192-204, 2000; Tornqvist, et al., Exp Neurol 164: 130-138, 2000) and as described in US 6,179,826, which disclosures are hereby incorporated
- 30 by reference in their entirety. FGF-22 may also be administered directly to the brain. In an additional embodiment of this invention, FGF-22 may also be employed to stimulate neuronal growth and to treat and prevent neuronal damage associated with stroke or which occurs in certain neuronal disorders or neurodegenerative conditions such as Alzheimer's and AIDS-related complex.
- 35 The Adeno Associated Virus (AAV) utilizes the human FGFR-1 as a co-receptor for infection in mammalian cells (Qing, et al., Nat Med 5: 71-77, 1999, which disclosures are hereby incorporated by reference in their entirety) as well as the ubiquitously expressed heparan sulfate

proteoglycans on cell surfaces. Similarly, adenoviral vectors are effectively targeted for the treatment of systemic and local disease using the ability of FGF family polypeptides to bind their cognate FGFR's with high affinity (Sosnowski, *et al.*, Curr Opin Mol Ther 1: 573-579, 1999, which disclosures are hereby incorporated by reference in their entirety). As a further embodiment of this invention is a method of retargeting a FGF-22 polypeptide or chimeric polypeptide encoded as part of an adenoviral or AAV delivery system to cells expressing cognate FGFR complexes using the methods of Hoganson, *et al.*, (Mol Ther 3: 105-112, 2001) and Qing, *et al.* (Nat Med 5: 71-77, 1999), which disclosures are hereby incorporated by reference in their entirety. Preferably the FGF-22 polypeptide is expressed, in part or in whole, with the viral delivery system as a bifunctional conjugate consisting of a blocking anti-adenoviral knob Fab fragment linked to FGF-22 using the methods of Goldman, *et al.* (Cancer Res 57:1447-51, 1997) and Doukas, *et al.* (FASEB J 13:1459-66, 1999). Preferably the FGFR complex is the FGFR-1 polypeptide or FGFR-1 polypeptide ligand binding moiety.

**Protein of SEQ ID NO:18 (Internal designation Clone 229633\_253-2-5-2-A11-F)**

The cDNA of Clone 229633\_253-2-5-2-A11-F (SEQ ID NO:17) encodes the STAM-SAPper (STAMSAP) protein comprising the amino acid sequence:  
MDRALQVLQSIDPTDSKPDSQDLLDLEDICQMGPIMIDEKLEEIDRKHSELSELNKVL  
LELYNKLNVNEAPVYSVYSKLHPPAHYPPASSGVPMQTYPVQSHGGNYMGQSIHQVTVAQ  
SYS LGPDQIGPLRSLPPNVNSSVTAQPAQTSYLS TGQDTVSNPTYMNQNSNLQSATGTTAY  
TQQMGMSVDMSSYQNTTSLNLPQLAGFPVTVPAHPVAQQHTNYHQPLL (SEQ ID  
NO:18). Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:18 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 229633\_253-2-5-2-A11-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:17 described throughout the present application also pertain to the nucleic acids included in Clone 229633\_253-2-5-2-A11-F. A preferred embodiment of the invention is directed toward the compositions comprising SEQ ID NO:17, SEQ ID NO:18, and Clone 229633\_253-2-5-2-A11-F. Another preferred embodiment of the invention is directed toward compositions comprising polynucleotide fragments of at least eighteen contiguous nucleotides selected from:  
gagcaagacgtggtgatgccaatgttggaaggagaaaatcac, preferably those polynucleotides that encode for polypeptides having a biological activity described herein. Further preferred polynucleotides of the present invention include nucleic acids comprising:  
gaagcggmgsggtctaggagccgcccgcgggtcaccgcgggtagcagttgctgagtgctagctagacagcagcgactagggtcgggcgccgcgcgagatgcctttgttcaccgccaacccttcgagcaagacgtggtgatgccaatgttggaaggagaaaatcac preferably those that encode for polypeptides having a biological activity described herein. Further preferred polynucleotides of the present invention include nucleic acids of SEQ ID NO:17 comprising

gaagcggmgsGGTctagggagccgcggccgcgggtcaccgcgggtagcagttgctgagtgctagctagacagcagcgactagggtc  
 cgggcgcggcgagatgcctttgtcaccgccaacccttcgagcaagacgtggtgatccaattggtggaaaggagaaaatcacagagga  
 ataggacttttccatccaatttgaacaactaatttaacatagagactgaggcagcggctgtggacaaattgaatgtaattgatgatgtgg  
 aggaaattaagaaatcagagcctgagcctgtttatagatgaggataagatggatagagccctgcaggtacttcagagtatagatccaacaga  
 5 tcaaaaccagactccaagaccttttgattagaagatatctgccaaca preferably those that encode for polypeptides  
 of having a biological activity described herein. Polypeptides of the invention having a biological  
 activity of x%, where x is any integer between 1 and 100 of those described herein and  
 polynucleotides encoding the same are also included in the invention. Polypeptides of the  
 invention with biological activity are defined as polypeptides that can be phosphorylated by a  
 10 tyrosine kinase such as a Janus kinase (Jak).

STAMSAP protein results from a splice event within the Signal Transducing Adaptor  
 Molecule (STAM)-2 transcript. This splice variant contacts or recombines nucleotide 152 of  
 STAM-2 with nucleotide 817. The resulting STAMSAP splice variant encodes the carboxy-  
 terminal 228 amino acids of the 525-amino acid STAM-2 protein. STAM-2 contains three well-  
 15 characterized domains. The first is an SH3 domain spanning amino acids 212-266 that is not  
 shared with STAMSAP. This SH3 domain binds the downstream effector of STAM-2, AMSH,  
 which activates proto-oncogenic transcription factors comprising c-myc and AP-1, and results in  
 responses that include cell proliferation (Tanaka, N., et al. (1999) J. Biol. Chem. 274:19129-35  
 which disclosure is hereby incorporated by reference in its entirety). An Immunoreceptor  
 20 Tyrosine-based Activation Motif (ITAM) spanning amino acids 359-387 of STAM-2 and a  
 carboxy-terminal tyrosine-rich domain are shared with STAMSAP (Endo, K., et al. (2000) FEBS  
 Let. 477:55-61 and Pandey, A., et al. (2000) J. Biol. Chem. 275:38633-9 which disclosures are  
 hereby incorporated by reference in their entireties).

STAMSAP is phosphorylated on tyrosine residues within the ITAM and carboxy-terminal  
 25 domains by Jak molecules comprising Jak2 and Jak3. Jak2 and Jak3 phosphorylate STAMSAP in  
 response to ligand binding of cell surface receptors comprising IL-2R, IL-3R, IL-4R, IL-7R,  
 Platelet Derived Growth Factor Receptor (PDGFR), Epidermal Growth Factor Receptor (EGFR),  
 and Granulocyte Macrophage Colony Stimulating Factor Receptor (GM-CSFR). Jak activation  
 and subsequent gene expression is associated with proliferation and cancers comprising breast and  
 30 colon carcinomas and B cell lymphomas (Yamauchi, T., et al. (2000) J. Biol. Chem. 275:33937-44;  
 Kaulsay, K., (2000) Endocrinology 141:1571-84; U.S. Patent 6177433 which disclosures are  
 hereby incorporated by reference in their entireties). Jak is often hyperactivated due to abnormally  
 high expression of upstream receptors or their ligands in cancer cells. For example, higher than  
 normal levels of PDGF are indicative of advanced stages of breast cancer (Seymour, L., et al.  
 35 (1993) Breast Cancer Res. Treat. 26:247-52 which disclosure is hereby incorporated by reference  
 in its entirety). EGFR is overexpressed in a variety of tumors including cervical cancer (Mathur,  
 R., et al. (2000) Am. J. Reprod. Immunol. 44:114-20 which disclosure is hereby incorporated by

reference in its entirety). Furthermore, Jak3 is activated in stimulated mast cells, causing degranulation and subsequent allergic reactions (U.S. Patent 6177433 which disclosure is hereby incorporated by reference in its entirety).

STAMSAP does not have a downstream effector and therefore acts as a dominant negative inhibitor of Jak signaling. In a preferred embodiment of the invention, the STAMSAP polypeptide is used to inhibit cell proliferation, cell survival, or viral replication downstream of Jak signaling. This embodiment is accomplished by methods comprising the step of delivering STAMSAP to cells responsive to activated Jak, for example, MOLT-4 cells expressing IL-2R (ATCC number CRL-1582). Methods for delivering STAMSAP to Jak-responsive cells include contacting said cells with STAMSAP polynucleotides or polypeptides by methods common to the art as discussed in the following paragraph. Further included in this embodiment is a polynucleotide comprising polynucleotides encoding a STAMSAP polypeptide with biological activity operably linked to an expression control element such as a promotor. Said polynucleotide is delivered to Jak-responsive cells by methods common to the art such as electroporation or transfection of naked polynucleotides. In addition, genes activated by Jak signaling may be monitored or assayed using methods common to the art, for example, reporter gene assays such as luciferase or beta-galactosidase. This embodiment is applied to, for example, inhibiting Jak-dependent cell responses in vitro.

Another preferred embodiment of the invention is directed towards methods to use STAMSAP to inhibit Jak-induced cell proliferation. In particular, this embodiment is directed toward inhibiting proliferation of cells resulting from activation of any upstream effector of Jak, such as a growth factor. Preferred upstream effector molecules include but are not limited to: PDGFR, EGFR, IL-2R, IL-3R, IL-4R, IL-7R, and GM-CSFR. STAMSAP is used in this method comprising the step of introducing a STAMSAP polypeptide or a polynucleotide comprising polynucleotides encoding said polypeptide operably linked to an expression control element into cells activated by Jak or any upstream effector of Jak (e.g., cervical cancer cells stimulated with EGF). Preferred control elements express an amount of STAMSAP effective to inhibit proliferation of cells to which the invention is delivered. Alternative preferred control elements comprise cell- or tissue-specific enhancer elements, for example, the lyn enhancer for B cells, or c-myc or AP-1 sites for proliferating cells. Said polypeptides or polynucleotides are introduced into said cells using methods common to the art, including but not limited to lipid vesicles or viral transduction, as described in any one of the list: U.S. Patent 5616565, U.S. Patent 6110490, U.S. Patent 6204060, or WO9704748 which disclosures are hereby incorporated by reference in their entireties. For example, polynucleotides are delivered to said cells by: i) compressing a polynucleotide expression unit, preferably an expression unit containing polynucleotides encoding biologically active STAMSAP polypeptide, into a lipid vesicle derived from any of the following list: viral envelopes, liposomes, micelles, and modified versions of these, as described in U.S.

Patent 6110490 or P.C.T.904748, which disclosures are hereby incorporated by reference in their entireties; ii) optionally targeting the lipid vesicle to specific cells, for example, by embedding a member of a receptor-receptor ligand pair into the lipid envelope (e.g., CD40 ligand for targeting to B cells); iii) contacting the targeted vesicle with specific cells by methods common to the art  
5 such as injection or inhalant (U.S. Patent 6110490, P.C.T. 9704748, and U.S. Patent 6034062 which disclosures are hereby incorporated by reference in their entireties). An example of delivering polypeptides to said cells comprises the steps: i) packaging a biologically active STAMSAP polypeptide into a lipid vesicle; ii) targeting the lipid vesicle to specific cells, for example, by including a member of a receptor- receptor ligand pair in the lipid envelope;  
10 iii) embedding a fusogenic component such as a peptide in the lipid envelope to promote delivery of encapsulated polypeptides to target cells; and iv) contacting the targeted vesicle with specific cells by injection or inhalant (P.C.T. 9704748 and U.S. Patent 6034062 which disclosures are hereby incorporated by reference in their entireties).

In another preferred embodiment, STAMSAP is used to inhibit Jak3 in cells that induce an  
15 inflammatory response, such as mast cells, eosinophils, T cells, and B cells. This embodiment includes a method to deliver a biologically active STAMSAP polypeptide or a polynucleotide comprising polynucleotides encoding said polypeptide operably linked to an expression control element to individuals displaying the effects of an inflammatory response (e.g., allergic rhinitis (hay fever), allergic urticaria (hives), angioedema, allergic asthma, or anaphylaxis). Preferred  
20 methods of delivery include but are not limited to a method comprising the steps: i) packaging of said polynucleotide into a lipid vesicle as described in U.S. Patent 6110490, U.S. Patent 5616565, and P.C.T. 9704748 which disclosures are hereby incorporated by reference in their entireties, and ii) delivering the vesicle to cells that induce an allergic response, such as mast cells, so that STAMSAP polypeptide is contacted with the relevant intracellular site. Preferred control elements  
25 direct expression of an amount of STAMSAP effective to inhibit an inflammatory response. Further preferred control elements for use in this embodiment include promoters of cell-specific genes such as CD48 in mast cells. The lipid vesicle is derived from any of the following list: viral envelopes, liposomes, micelles, and modified versions of these. Targeting of vesicles to specific cell types, as referred to in step (ii), is effected by embedding a targeting moiety such as a member  
30 of a receptor- receptor ligand pair into the lipid envelope of the vesicle. Useful targeting moieties specifically bind cell surface ligands, such as CD48 or the SCF receptor on mast cells. Thus, anti-CD48 antibodies or SCF ligand are examples of useful mast cell-targeting moieties. In addition, the antibodies B43 and TXU are useful for B and T cells, respectively. Vectors and targeting are further described in U.S. Patent 6177433, U.S. Patent 6110490, and P.C.T. 9704748, which  
35 disclosures are hereby incorporated by reference in their entireties. The invention is delivered to the appropriate site by methods common to the art such as injection or inhalant as described in U.S. Patent 6177433 and U.S. Patent 6034062, which disclosures are hereby incorporated by reference

in their entirety.

**Protein of SEQ ID NO:22 (Internal designation Clone 589198\_184-11-1-0-E4-F)**

The cDNA of Clone 589198\_184-11-1-0-E4-F (SEQ ID NO:21) encodes the Corneal Osteo-Vascular Inducing (COVI) protein comprising the amino acid sequence:

- 5 MKTLQSTLLLLLVPLIKPAPPTQQDSRIIYDYGTDNFEESIFSQDYEDKYLDGKNIKEKET  
VIIPNEKSLQLQKDEAITPLPPKKENDEMPCTLLCVCLSGSVYCEEVDIDAVPPLPKESAYL  
YARFNKIKKLTAKDFADIPNLRRLDFTGNLIEDIEDGTFSKLSLLEELSLAENXLLKLPVLPP  
KLTLFNAKYNKIKSRGIKANAFKKLNLTFLYLDHNALESVPLNLPESLRVIHLQFNNIASI  
TDDTFCKANDTSYIRDRIEEIXLEGNPVLGKHPNSFICKRLPIGSYF (SEQ ID NO:22).
- 10 Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:22 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 589198\_184-11-1-0-E4-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:21 described throughout the present application also pertain to the nucleic acids included in Clone 589198\_184-11-1-0-E4-F.
- 15 A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:21, SEQ ID NO:22, and Clone 589198\_184-11-1-0-E4-F. Further included in the invention are polypeptide fragments at least seven amino acids in length of SEQ ID NO:22 and those having a biological activity of those described herein and polynucleotides encoding the same. Biological activities include but are not limited to increasing bone density when contacted with osteogenic
- 20 cells and remodeling of vascular tissue.

The COVI polypeptide is a unique splice variant of the mimecan (also called osteoglycin and osteoinductive factor) gene (Kukita, A., et al. (1990) Proc. Natl. Acad. Sci. 87:3023-6, Funderburgh, J., et al. (1997) J. Biol. Chem. 272:28089-95, and Tasheva, E., et al. (1999) J. Biol. Chem. 274:18693-701 which disclosures are hereby incorporated by reference in their entirety).

- 25 The 1997 base pair COVI transcript begins in exon 3 of full-length mimecan and encodes a 298 amino acid protein.

- The COVI polypeptide is a secreted protein associated with the extracellular matrix (ECM) that promotes growth and remodeling of bone. In a preferred embodiment of the invention, COVI polypeptide is used in a method to promote bone growth by contacting a bone growth-stimulating
- 30 effective amount of COVI polypeptide with cells. Preferred cells are those that normally produce bone tissue, including but not limited to osteoblasts, osteocytes, and their precursors. This method is useful to facilitate bone growth in cases including but not limited to bone loss, atrophy, or malformation due to injury, congenital or chronic conditions, surgery, or disease. Examples include but are not limited to osteopenia, osteoporosis, rickets, malignant melanoma-induced bone
- 35 degradation, and bone fissures or fractures due to injury, elective surgery (e.g., plastic surgery), reconstructive surgery, and dental procedures or surgeries. COVI polypeptides are delivered in a physiologically acceptable solution, for example, pH-buffered saline, viscous solutions such as

those including glycerol or dextrose, or in solutions that include other components to support bone growth. Preferred bone growth components comprise bone fragments, ground bone, and matrix materials including calcium sulfate, hydroxyapatite, ultrahigh molecular weight polyethylene (UHMWPE), and proteins such as collagen. COVI polypeptides in physiologically acceptable solution are delivered locally or systemically (as the case dictates) by methods including but not limited to injection, catheter delivery, or direct implantation (U.S. Patent 6,034,062 which disclosures are hereby incorporated by reference in their entirety).

A further embodiment of the invention is a method of contacting a bone growth-stimulating amount of COVI polypeptide with cells to facilitate integration of bone, for example, for purposes of bone transplantation in cases of dental implants, orthopedic prosthesis, or other surgical procedures. Preferred cells are those present in bone tissue, including but not limited to osteoblasts, osteocytes, and their precursors. COVI polypeptides are delivered in a physiologically acceptable solution, for example, pH-buffered saline, viscous solutions such as those including glycerol or dextrose, or in solutions that include other components to support bone growth. Preferred bone growth components comprise bone fragments, ground bone, and matrix materials including calcium sulfate, hydroxyapatite, UHMWPE, and proteins such as collagen. COVI polypeptides in physiologically acceptable solution are delivered to the site of desired bone integration by methods comprising injection or direct addition to the integrated tissue (U.S. Patent 6034062, which disclosure is hereby incorporated by reference in its entirety).

A further embodiment of this invention is a method of contacting a growth-stimulating amount of COVI polypeptide with cells to facilitate bone growth for example, for purposes of transplantation. Preferred cells include bone cells. Further preferred cells include but are not limited to human osteoblast cells, for example the cell lines MG63 or C2C12 or osteoblasts purified directly from bone, or their progenitors, such as those purified from bone marrow stroma or mesenchymal stem cells. Preferred culture conditions are common to the art and can include but are not limited to other factors to promote bone formation, for example bone or composite matrices to direct shaping, ascorbic acid, beta-glycerophosphate, dexamethasone, calcium salts, and collagen [Dean, D., et al. (2001) J. Orthop. Res. 19:179-86 and Buttery, L., et al. (2001) Tissue Eng. 7:89-99, which disclosures are hereby incorporated by reference in their entirety]. A preferred method comprises the steps: contacting COVI polypeptide directly with cells in culture; harvesting mineralized bone formation; and surgically implanting newly formed bone into desired location (U.S. Patent 4950296, U.S. Patent 5385566, and U.S. Patent 6200324, which disclosures are hereby incorporated by reference in their entirety). Another preferred method comprises the steps: delivering polynucleotides to cells in culture; delivering cells to sites of desired bone growth (for example, to the site of a fracture or to an osteopenic bone). Preferred polynucleotides comprise polynucleotides encoding COVI polypeptide operably linked to an expression control unit (e.g., a promoter) that will deliver a bone growth-stimulating amount of COVI expression (for

example, high, constitutive expression from the CMV promoter or regulated expression from a tetracycline-repressible promoter, both of which are readily commercially available). Said polynucleotides are delivered to cells in vitro or in situ by methods common to the art such as electroporation, calcium phosphate transfection, or adenoviral transduction [Maniatis, T., et al.

- 5 Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory (1982) and Cheng, S., et al. (2001) *Calcif. Tissue Int.* 68:87-94, which disclosures are hereby incorporated by reference in their entireties]. Cells are introduced to a site of desired bone growth in vitro, in situ, or in vivo by methods comprising injection, introduction through a catheter, or surgical implantation of a cell-containing stent, for example, on an osteopenic bone (U.S. Patent 6034062 and U.S. Patent 10 6206914, which disclosures are hereby incorporated by reference in their entireties).

- COVI is associated with vascular smooth muscle cells (VSMC) in the ECM. The COVI splice variant has enhanced ability to promote vascular matrix remodeling, i.e., formation of new vessels (e.g., during development or tissue expansion), and healing of damaged vessels such as those resulting from injury, incision, burns, disease, cardiac infarction, ulcers, diabetic ulcers, and 15 chronic conditions such as atherosclerosis. A preferred embodiment of the invention is a method to promote vascular remodeling by contacting a vascular remodeling-stimulating amount of COVI polypeptide with cells. Preferred cells include but are not limited to VSMC, vascular epithelial cells, and fibroblasts. Further preferred cells include but are not limited to human VSMC, vascular epithelial cells, and fibroblasts in intact tissue (i.e., in a milieu of ECM proteins such as collagen).
- 20 COVI polypeptides are delivered to cells in physiologically acceptable solution, for example, pH-buffered saline or viscous solutions such as those including glycerol or dextrose. Said solution may be applied topically to surface wound tissue in the treatment of ulcers, lesions, injuries, diabetic ulcers, burns, trauma, stasis ulcers, periodontal conditions, lacerations, and other conditions. In addition, intraperitoneal wound tissue such as that resulting from invasive surgery 25 may be treated with a physiologically acceptable solution comprising COVI polypeptides to accelerate vascular remodeling. For example, the surgical plane may be coated with said solution prior to closing the surgical site to facilitate internal capillary perfusion and healing. In addition, the rate of localized healing may be increased by the subdermal administration of said solution by methods common to the art such as injection (U.S. Patent 6,096,709, which disclosure is hereby 30 incorporated by reference in its entirety).

- Timely vascular remodeling is an urgent factor in the case of cardiac infarction to prevent enlargement of the organ. A further preferred embodiment of the invention is a method of contacting a vascular remodeling-stimulating amount of COVI polypeptide with cells. The method comprises the step of contacting COVI polypeptides with cells by implantation of a COVI 35 polypeptide-releasing stent, for example surgically or via catheter (U.S. Patent 5,500,013 and U.S. Patent 5,449,382, which disclosures are hereby incorporated by reference in their entireties). Preferred cells include but are not limited to those found in cardiac tissue damaged as a result of

infarction or within vessels for treating various problems such as atherosclerosis, stenoses, strictures, or aneurysms to reinforce collapsing, partially occluded, or weakened sections.

A further preferred embodiment of the invention is a method to promote vascular remodeling by delivering polynucleotides encoding COVI polypeptides to cells. This method is directed toward purposes such as transplantation of cells expressing COVI polypeptides. Preferred cells include but are not limited to VSMC, vascular epithelial cells, and fibroblasts. Further preferred cells include but are not limited to human VSMC, vascular epithelial cells, and fibroblasts, preferably in intact tissue (i.e., in a milieu of ECM proteins such as collagen). Preferred polynucleotides comprise polynucleotides encoding COVI polypeptides operably linked to an expression control unit (e.g., a promoter) that will deliver a vascular remodeling-stimulating amount of COVI expression (for example, high, constitutive expression from the CMV promoter or regulated expression from a tetracycline-repressible promoter, both of which are readily commercially available). Said polynucleotides are delivered to cells in vitro or in situ by methods common to the art such as electroporation, calcium phosphate transfection, or adenoviral transduction [Maniatis, T., et al., Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory (1982) and Cheng, S., et al. (2001) Calcif. Tissue Int. 68:87-94, which disclosures are hereby incorporated by reference in their entireties]. Further included in the method is a step of delivering said cells to a desired site of vascular remodeling (including but not limited to wounds, incisions, injuries, ulcers, and diseased or otherwise hypovascular lesions) by methods common to the art such as injection or catheter delivery of cell suspensions or surgical implantation of intact tissue endoscopically or invasively (U.S. Patent 5,669,925 and U.S. Patent 5,683,345, which disclosures are hereby incorporated by reference in their entireties).

COVI polypeptide is also present as a highly modified keratan sulfate proteoglycan (KSPG) in the cornea. KSPG's are associated with ECM proteins in the cornea and function to maintain corneal shape and opacity. In a further embodiment of the invention, a cornea-maintaining effective amount of COVI polypeptide is used in a method for maintaining a desired shape (e.g., following laser surgery or non-invasive orthokeratological procedures) or opacity of corneal tissues (e.g., at the onset of cataract formation). This method comprises the step of contacting COVI polypeptides with the ECM of the cornea in a physiologically acceptable solution. A preferred physiologically acceptable solution includes pH-buffered saline. Preferred method of contact is by an eye-drop mechanism (P.C.T. 00119386, which disclosure is hereby incorporated by reference in its entirety).

**Protein of SEQ ID NO:4 (Internal designation Clone 1000848582\_181-40-4-0-A11-F)**

The cDNA of clone 1000848582\_181-40-4-0-A11-F (SEQ ID NO:3) encodes the protein of SEQ ID NO:4 comprising the amino acid sequence

MELALRRSPVPRWLLLLPLLLGLNAGAVIDWPTEEGKEVWDYVTVRKDAYMFWWLYY  
ATNSCKNFSELPLVMWLQGGPGGSSTGFGNFEEIGPLDSDLKPRKTTWLQAASLLFVDNP  
VGTGFSYVNGSGAYAKDLAMVASDMMVLLKTTFFSCHKEFQTVPFYIFSESYGGKMAAGI

GLELYKAIQRGTIKCNFAGVALGDSWISPVDSVLSWGPYLYSMSLLEDKGLAEVSKVAEQ  
VLNAVNKGLYREATELWGKAEMIEQVKGNTQRLACLAFFSGGYRAHGWCCQTWSLH.

Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:4 described throughout the present application also pertain to the polypeptides encoded by the  
5 nucleic acids included in Clone 1000848582\_181-40-4-0-A11-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:3 described throughout the present application also pertain to the nucleic acids included in Clone 1000848582\_181-40-4-0-A11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:3, SEQ ID NO:4, and Clone 1000848582\_181-40-4-0-A11-F. Also preferred are polypeptide  
10 fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:4 encodes a novel serine carboxypeptidase designated here serine carboxypeptidase hx (SCPhx). SCPhx has a unique C-terminal sequence of 31 amino acids comprising KRGNTQRLACLAFFSGGYRAHGWCLQTWSLH. This unique sequence within  
15 SCPhx contributes the histidine of the catalytic triad. SCPhx cleaves the peptide bond between the penultimate and C-terminal amino acid residues of its protein or peptide substrate and, in so doing, can either activate or inactivate the biological function of the substrate.

A preferred embodiment of the invention is directed to compositions comprising the amino acid sequence of SEQ ID NO:4 (SCPhx) or fragments thereof.

20 Further preferred is a method to use the serine carboxypeptidase activity of compositions comprising SCPhx polypeptide for biosynthetic procedures. Further preferred is an application of said method wherein a recombinant polypeptide engineered with a protective but inactivating C-terminal amino acid is activated through removal of this amino acid by SCPhx.

Further preferred is a method to use the serine carboxypeptidase activity of compositions  
25 comprising SCPhx polypeptide for analytical procedures. Further preferred is an application of said method wherein the requirement for the C-terminal amino acid for the function of a given protein is determined through removal of the amino acid by SCPhx.

The serine carboxypeptidase activity of SCPhx confers on SCPhx antifibrinolytic activity. In a further embodiment, compositions of the invention comprised of SCPhx are used in methods  
30 wherein the antifibrinolytic activity of SCPhx is used to promote wound healing. In further preferred embodiment, the composition is used in methods of stabilizing blood clots at sites where there is a breach in the vasculature by contacting a wound or injured tissue with a regenerative-effective amount of compositions of the invention.

In a further embodiment of the invention, SCPhx is used in a method for antibody-directed  
35 enzyme prodrug therapy (ADEPT). In said method, in vivo localization of SCPhx serine carboxypeptidase activity is effected through conjugation of SCPhx to specific antibody. Injection of SCPhx-antibody conjugate in conjunction with prodrug (drug-alpha-peptide) (Shi, P.T., et al.,

Yao Xue Bao 32:106-9 (1997) which disclosure is hereby incorporated by reference in its entirety) results in localized activation of the drug.

In said method for ADEPT, a preferred embodiment of the invention is directed to compositions comprising SCPhx conjugated to tumor-reactive antibody [Napier, M.P., et al., Clin. 5 Cancer Res. 6:765-72 (2000) which disclosure is hereby incorporated by reference in its entirety]. In further preferred embodiment, SCPhx is conjugated to antibody reactive with carcinoembryonic antigen (CEA) and is used in conjunction with methotrexate prodrug for the treatment of colorectal carcinoma.

In a further preferred embodiment, the present invention provides for an antibody that 10 binds SCPhx with or without neutralization of SCPhx serine carboxypeptidase activity. The antibody may be monoclonal or polyclonal. Preferred compositions comprise the SCPhx antibody.

SCPhx serine carboxypeptidase activity expressed by breast cancer cells can activate autocrine neuropeptide growth factors concomitantly expressed by the tumor cells. In further 15 embodiment of the invention, neutralizing anti-SCPhx antibody is used by intravenous injection to suppress tumor growth by blocking the activation of autocrine growth factors by SCPhx constitutively expressed by the tumor. In further preferred embodiment, said method is used for the treatment of breast cancer. In further preferred embodiment, said method is used for the treatment of cancer of the salivary gland.

SCPhx serine carboxypeptidase activity can process beta-amyloid precursor protein and 20 generate beta-amyloid. In further embodiment of the invention, neutralizing anti-SCPhx antibody is used by injection in Alzheimer's disease to block processing of beta-amyloid precursor protein and generation of beta-amyloid.

Daily administration of a very low dose of the polypeptide gAcrp30 to mice consuming a high-fat/sucrose diet causes profound and sustainable weight reduction without affecting food 25 intake (Fruebis, J., et al., Proc. Natl. Acad. Sci. USA 98:2005-10 (2001) which disclosure is hereby incorporated by reference in its entirety). Said activity of gAcrp30 is abrogated by SCPhx serine carboxypeptidase activity. In a preferred embodiment of the invention, compositions comprising said neutralizing SCPhx antibody are used in methods to block in vivo inactivation of polypeptide function by SCPhx serine carboxypeptidase activity. In further preferred embodiment, 30 compositions comprising said neutralizing SCPhx antibody are used in methods to treat obesity in humans by intravenous injection concomitant with human gAcrp30. In further preferred embodiment, compositions comprising said neutralizing SCPhx antibody are used in methods to treat obesity in other mammals by intravenous injection concomitant with mammal or human gAcrp30.

35 The invention further relates to a method of screening for test compounds that bind and/or inhibit SCPhx serine carboxypeptidase activity above comprising the steps of contacting an SCPhx polypeptide with said test compound and detecting or measuring whether said test compound binds

said SCPhx polypeptide. Alternatively, the method comprises the steps of contacting an SCPhx polypeptide with substrate of said SCPhx polypeptide in the presence of test compound and detecting or measuring the release of the C-terminal amino acid from said SCPhx substrate, wherein a difference in the amount of said release relative to the amount of release in the absence of the test compound modulates, preferably inhibits, the serine carboxypeptidase activity of SCPhx.

**Protein of SEQ ID NO:8 (Internal designation Clone 1000770704\_208-27-3-0-G6-F)**

The cDNA of clone 1000770704\_208-27-3-0-G6-F (SEQ ID NO:7) encodes the protein of SEQ ID NO:8 comprising the amino acid sequence

10 MRLPAQLLGLLMLWVSGSSGDIVMTQSPLFLPVTGPGEPAISCRSSQSLLHVQGSNYLDW  
YHQPQGPQSPQLLIYLGSNRASGVDPDRFSGSGSGTDFTLKISRVEAEDVGVYYCMQALQTPF  
TFGPGTRVDIKRTVAAPSVFIFPPSDEQLKSGTASVVCLLNNFYPREAKVQWKVDNALQS  
GNSQESVTEQDSKSTYLSSTLTLSKADYEKHKVYACEVTHQGLSSPVTKSFNRGEC.

Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:8 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 1000770704\_208-27-3-0-G6-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:7 described throughout the present application also pertain to the nucleic acids included in Clone 1000770704\_208-27-3-0-G6-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:7, SEQ ID NO:8, and Clone 1000770704\_208-27-3-0-G6-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:8 encodes the polypeptide CalX, which binds parathyroid hormone related protein (PTHrP), a hormone involved in bone metabolism.

25 PTHrP was initially discovered as a tumor-derived systemic factor that causes humoral hypercalcemia of malignancy (HHM). PTHrP is now known to play a major role in HHM. It has been identified as the major causative agent in tumors that were previously thought to cause hypercalcemia through skeletal metastatic involvement. Hypercalcemia is the most common life-threatening metabolic disorder associated with neoplastic diseases, occurring in an estimated 10% to 20% of all persons with cancer. That PTHrP is not just a bystander but is the cause of the hypercalcemia is indicated by the observation that in animals with hypercalcemia caused by xenografts of human tumors, the infusion of neutralizing antibodies to PTHrP reverses the hypercalcemia.

CalX binds to and neutralizes the activity of PTHrP, including the induction of HHM. A preferred embodiment of the invention is directed to comprising the amino acid sequence of SEQ ID NO:8 (CalX). Further included in the invention are fragments of full-length CalX having a biological activity described herein as well as the polynucleotides encoding these fragments.

In a preferred embodiment, compositions of the invention are used in methods to neutralize PTHrP, wherein compositions comprising CalX are contacted with and thereby block PTHrP activity. A further embodiment is directed toward a method to use compositions of CalX to suppress HHM. In further preferred embodiment, CalX is used to suppress HHM associated with breast cancer, pancreatic adenocarcinoma, prostate cancer, squamous cell carcinoma of lung, renal cell carcinoma, ovarian carcinoma, and T cell leukemia/lymphoma.

It is believed that PTHrP plays a role in the pathophysiology associated with osteoarthritis. In further preferred embodiment, CalX is used in a method to suppress bone resorption within an affected joint, preferably in the synovium of a joint capsule. Said methods comprise contacting CalX compositions with the synovial fluid of the joint capsule. Preferred delivery of CalX includes injection or transdermal contact at the site of the joint.

It is believed that PTHrP plays a role in the pathophysiology associated with rheumatoid arthritis. In further preferred embodiment, CalX is used in a method to decrease inflammation within an affected joint, preferably in the synovium of a joint capsule. In further preferred embodiment, CalX is used in a method to decrease bone resorption within an affected joint, preferably in the synovium of a joint capsule. Said methods comprise contacting CalX compositions with the synovial fluid of the joint capsule. Preferred delivery of CalX includes injection or transdermal contact at the site of the joint.

**Protein of SEQ ID NO:6 (Internal designation Clone 1000839315\_220-26-1-0-F3-F)**

The cDNA of clone 1000839315\_220-26-1-0-F3-F (SEQ ID NO:5) encodes the protein of SEQ ID NO:6 comprising the amino acid sequence:  
MKFFVFALVLALMISMISADSHEKRHHGYRRKFHEKHHSYHITLLPLFESSKSNANEKHY  
NLLYTLCFRILAFSIVT. Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:6 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 1000839315\_220-26-1-0-F3-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:5 described throughout the present application also pertain to the nucleic acids included in Clone 1000839315\_220-26-1-0-F3-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:5, SEQ ID NO:6, and Clone 1000839315\_220-26-1-0-F3-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:6 encodes Chimerin, a chimeric polypeptide encoded by an exon derived from the histatin 1 gene spliced downstream onto an exon derived from the linked statherin gene. Specifically, an exon encoding the N-terminal amino acids of both histatin 1 and Chimerin (MKFFVFALVLALMISMISADSHEKRHHGYRRKFHEKHHS) is spliced onto a statherin-derived exon that encodes the novel C-terminal amino acids of Chimerin (YHITLLPLFESSKSNANEKHYNLLYTLCFRILAFSIVT) but in contradistinction entirely 3'-

untranslated nucleotide sequence in statherin mRNA.

Chimerin is a low molecular weight, histidine-rich salivary polypeptide. Chimerin functions as part of the nonimmune host defence system in the oral cavity.

Chimerin possesses broad spectrum antifungal activity, including that against the pathogenic yeast *Candida albicans*, with minimal cytotoxicity towards normal host cells, suggesting its high potential as a novel anti-fungal therapeutic agent. Chimerin also possesses antibacterial activity, including that against *Streptococcus mutans* strains and the periodontopathogenic *Porphyromonas gingivalis*. A great benefit of Chimerin is that to date no resistant fungal strains have been demonstrated and moreover, that Chimerin can be hydrolyzed in a natural way in the digestive tract. Therefore, Chimerin might be applied for long term use, intermitting the application of antibiotics.

A preferred embodiment of the invention is directed to compositions comprising the amino acid sequence of SEQ NO:6 (Chimerin)

MKFFVFALVLALMISMISADSEKRRHHGYRRKFHEKHHSYHITLLPLFEESSKSNANEKHY  
 15 NLLYTLCFRILAFSIVT.

Further included in the invention are fragments of the full-length Chimerin polypeptide having a biological activity described herein as well as the polynucleotides encoding these fragments. Preferred fragments with biological activity include the amino acid sequence comprising

20 DSHEKRHHGYRRKFHEKHHSYHITLLPLFEESSKSNANEKHYNLLYTLCFRILAFSIVT or  
 DSHEKRHHGYRR or  
 KFHEKHHSYHITLLPLFEESSKSNANEKHYNLLYTLCFRILAFSIVT.

Further preferred is a method to use formulations comprising Chimerin in a physiologically compatible solution as further described in US Patent 4,725,576 ("Fungicidal polypeptide compositions containing L-histidine and methods for use therefore") and incorporated by reference in its entirety, including but not limited to the incorporation of Chimerin into a mouth wash.

Further preferred is a method to use compositions comprising Chimerin as agents with which to treat a fungal or bacterial infection as further described in US Patent 5,912,230 ("Anti-fungal and anti-bacterial histatin-based peptides") and incorporated by reference in its entirety. The said method is comprised of contacting said fungi and bacteria with an effective amount of Chimerin polypeptide of the present invention. Said method for treating a fungal or bacterial infection of claim is applicable when said fungal or bacterial infection is selected from the group consisting of: (a) an infection of the oral cavity; (b) an infection of the vagina; (c) an infection of the urethra; (d) an infection of the ear; (e) an infection of the skin; (f) a respiratory infection; (g) a mucosal infection; (h) an ophthalmic infection; and (i) systemic infection.

Further preferred is a method to use compositions comprising Chimerin as described as

agents with which to prevent recurring fungal or bacterial infection in patients including, but not limited to, those from the group consisting of: AIDS patients; diabetics; and xerostomia patients, including patients with Sjogren's syndrome and those patients whose salivary gland function has been compromised as a result of radiation therapy.

- 5 Further preferred is method to use compositions comprising Chimerin for treating a fungal or bacterial infection wherein the fungus or bacterium is selected from the group consisting of:
- (a) *Candida albicans*; (b) *Actinomyces actinomycetemcomitans*; (c) *Actinomyces viscosus*;
  - (d) *Bacteroides forsythus*; (e) *Bacteriodes fragilis*; (f) *Bacteriodes gracilis*; (g) *Bacteriodes ureolyticus*; (h) *Campylobacter concisus*; (i) *Campylobacter rectus*; (j) *Campylobacter showae*;
  - 10 (k) *Campylobacter sputorum*; (l) *Capnocytophaga gingivalis*; (m) *Capnocytophaga ochracea*;
  - (n) *Capnocytophaga sputigena*; (o) *Clostridium histolyticum*; (p) *Eikenella corrodens*;
  - (q) *Eubacterium nodatum*; (r) *Fusobacterium nucleatum*; (s) *Fusobacterium periodonticum*;
  - (t) *Peptostreptococcus micros*; (u) *Porphyromonas endodontalis*; (v) *Porphyromonas gingivalis*;
  - (w) *Prevotella intermedia*; (x) *Prevotella nigrescens*; (y) *Propionibacterium acnes*;
  - 15 (z) *Pseudomonas aeruginosa*; (aa) *Selenomonas noxia*; (bb) *Staphylococcus aureus*;
  - (cc) *Streptococcus constellatus*; (dd) *Streptococcus gordonii*; (ee) *Streptococcus intermedius*;
  - (ff) *Streptococcus mutans*; (gg) *Streptococcus oralis*; (hh) *Streptococcus pneumonia*;
  - (ii) *Streptococcus sanguis*; (kk) *Treponema denticola*; (ll) *Treponema pectinovorum*;
  - (mm) *Treponema socranskii*; (nn) *Veillonella parvula*; and (oo) *Wolinella succinogenes*.

- 20 The compositions and methods for treatment of fungal and bacterial infections discussed above are not limited to use in humans, but can have veterinary applications as well.

In a further preferred embodiment, the present invention provides for an antibody that specifically binds Chimerin. The invention further relates to a method of screening for antibodies that specifically bind Chimerin comprising the steps of contacting the unique C-terminal 39 amino acids of Chimerin (YHITLLPLFEESKSNANEKHYNLLYTLCFRILAFSIVT) with said test antibody and detecting or measuring whether said test antibody binds said Chimerin polypeptide.

25 Further preferred is a method to use compositions comprising this antibody in diagnostic assays to measure Chimerin concentration in bodily fluids, including saliva.

- Further preferred is a method to use compositions comprising this antibody to specifically purify Chimerin from bodily fluids, including saliva, or from recombinant sources utilizing compositions comprising the nucleotide sequence of SEQ NO:5 (Chimerin) or fragments thereof.

**Protein of SEQ ID NO:2 (Internal designation Clone 223583\_114-044-2-0-E11-F)**

The cDNA of clone 223583\_114-044-2-0-E11-F (SEQ ID NO:1) encodes the protein of SEQ ID NO:2 comprising the amino acid sequence:

- 35 MAACQLLEITTFLETFSCLP RPRT EPLVASTDHTKMPSQMEHAMETMMFTFHKFAGDK  
GYLTKEDLRVLMKEKEFGFLENQKDPLAVDKIMKDLDQCRDGKVGFGQSFFSLIAGLTIAC  
NDYFVVHMKQKGKK. Accordingly it will be appreciated that all characteristics and uses of

polypeptides of SEQ ID NO:2 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 223583\_114-044-2-0-E11-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:1 described throughout the present application also pertain to the nucleic acids included in Clone 223583\_114-044-2-0-E11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:1, SEQ ID NO:2, and Clone 223583\_114-044-2-0-E11-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:2 encodes S-100A10 Related Protein (S-100A10rP), which is a splice variant of S-100A. Specifically, the protein of SEQ ID NO:2 encodes the S-100A10 polypeptide preceded by a unique sequence of 37 amino acids at the amino terminus comprising MAACQLLLEITTFLETFSCLP RPTEP LVASTDHTK.

Dimeric S-100A10 can associate with dimeric annexin II to form a heterotetramer. As a component of this heterotetramer, S-100A10 can mediate a number of activities at the cell surface (Kassam G., et al., Biochemistry 37:16958-66 (1998), Mai, J., et al., J. Biol. Chem. 275:12806-12 (2000) which disclosures are hereby incorporated by reference in their entirety). S-100A10rP antagonizes these activities.

Heterotetrameric annexin II at the cell surface promotes the generation of plasmin, a serine protease with broad substrate specificity, through its association with both plasminogen and tissue plasminogen activator. The promotion of plasmin generation by annexin II plays a role in: (i) control of hemostasis and coagulation, (ii) macrophage migration and matrix remodeling, (iii) neuronal cell differentiation, (iv) tumor cell invasion and metastasis, and (v) cardiovascular development and angiogenesis.

A preferred embodiment of the invention is directed to compositions comprising the amino acid sequence of SEQ NO:2 (S-100ArP). Further preferred embodiment of the invention is directed to compositions comprising either monomeric or dimeric S-100A10rP. Further included in the invention are fragments of the full-length S-100A10rP polypeptide having a biological activity described herein as well as the polynucleotides encoding these fragments.

Further preferred is a method to use compositions comprising S-100ArP to suppress plasmin generation and thereby decrease inflammation at sites of chronic inflammation, preferably in the synovium of a joint capsule. Said methods comprise contacting S-100A10rP compositions with the synovial fluid of the joint capsule. Preferred delivery of S-100A10rP includes injection or transdermal contact at the site of the joint.

Preferred is a method to use compositions comprising S-100ArP to suppress tumor cell metastasis. Further preferred is an embodiment of the method directed to the use of compositions of S-100A10rP to suppress tumor cell metastasis facilitated by the binding of the cysteine protease cathepsin B to cell surface heterotetrameric annexin II. Said method is comprised of contacting said

tumor cells with an effective dose of S-100A10rP by injection. Further preferred is an embodiment of the method directed to the use of S-100A10rP to suppress the metastasis of breast cancer. Further preferred in an embodiment of the method directed to the use of S-100A10rP to suppress the metastasis of glioma.

- 5 Preferred is a method to use compositions comprising S-100ArP to suppress inflammation associated with wound healing. Further preferred are compositions comprised S-100ArP used in methods of treatment comprised of contacting a wound or injured tissue with an ameliorative effective amount by injection or transdermal contact at the site of the wound.

Acute promyelocytic leukemia (APL) is characterized by hyperfibrinolysis due to  
10 heterotetrameric annexin II promoted plasmin generation and a consequential disseminated intravascular coagulation. In a preferred embodiment of the invention, S-100A10rP is used to suppress this hyperfibrinolysis. Said method is comprised of contacting APL cells with an effective amount of S-100A10rP by injection.

A preferred embodiment of the invention is to use compositions comprising S-100A10rP  
15 in a method to suppress angiogenesis associated with the growth of solid tumors. Further preferred is a method to use compositions comprising S-100A10rP to suppress angiogenesis associated with breast cancer, prostate cancer, pancreatic adenocarcinoma, colorectal cancer, renal cell carcinoma, squamous cell carcinoma of the lung, and T cell lymphoma. Preferred delivery includes contacting the tumor with an effective amount of S-100A10rP by intravenous injection.

20 A preferred embodiment of the invention is to use compositions comprising S-100A10rP in a method to suppress angiogenesis associated with chronic inflammation. Further preferred is a method to use compositions comprising S-100A10rP to suppress angiogenesis associated with rheumatoid arthritis and thereby decrease inflammation, preferably in the synovium of a joint capsule. Said methods comprise contacting S-100A10rP compositions with the synovial fluid of  
25 the joint capsule.

In a further preferred embodiment, the present invention provides for an antibody that specifically binds an S-100A10rP polypeptide of the present invention in a method of neutralizing S-100A10rP function and thereby up-regulating the functional activity of extracellular heterotetrameric annexin II. Further preferred is a method to use compositions comprising this  
30 antibody to promote angiogenesis in ischemic heart tissue. Preferred delivery includes contacting the heart tissue with an effective amount of anti-S-100A10rP antibody by intravenous injection. Further preferred is a method to use compositions comprising anti-S-100A10rP antibody to promote neuritogenesis in ischemic brain tissue. Preferred delivery includes contacting the neural tissue with an effective amount of anti-S-100A10rP antibody by local injection or transdermal  
35 contact.

**Protein of SEQ ID NO:32 (Internal designation clone 477709\_174-8-2-0-C10-F)**

The cDNA of Clone 477709\_174-8-2-0-C10-F (SEQ ID NO:31) encodes the protein of SEQ ID

NO:32 comprising the amino acid sequence :

MAWRGWAQRGWGCGQAWGASVGGRSCEELTAVLTPPQLLGRRFNFFIQQKCGFRKAPR  
KVEPRRSDPGTSGEAYKRSALIPPVEETVFYFSPYPYPIRSLIKPLFFTVGFTGCAFGSAAIWQY  
ESLKSRVQSYFDGIKADWLDLSIRPQKEGDFRKEINKWWNNLSDGQRTVTGIIAANVLVFC  
5 LWRVPSLQRTMIRYFTSNPASKVLCSPMLLSTFSHSLFHMAANMYVLWSFSSSIVNILGQ  
EQFMAVYLSAGVISNFVSYVGKVATGRYGPSLGAALKAIAMDTAGMILGWKFFDHAHAH  
LGGALFGIWYVTYGHელიWKNREPLVKIWHEIRTNGPKKGGGSK. Accordingly, it will be

- appreciated that all characteristics and uses of polypeptides of SEQ ID NO:32 described  
throughout the present application also pertain to the polypeptides encoded by the nucleic acids  
10 included in Clone 477709\_174-8-2-0-C10-F. In addition, it will be appreciated that all  
characteristics and uses of the polynucleotides of SEQ ID NO:31 described throughout the present  
application also pertain to the nucleic acids included in Clone 477709\_174-8-2-0-C10-F. A  
preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:31,  
SEQ ID NO:32, and Clone 477709\_174-8-2-0-C10-F. Also preferred are polypeptide fragments  
15 having a biological activity as described herein and the polynucleotides encoding the fragments.

- The protein of SEQ ID NO:32 encodes Pretactilin, a splice variant of the protein of EMBL  
entry Q9H300. The corresponding locus located on chromosome 3 possesses at least 2 known  
variants described in entries AAH03653 and Q9H300 in EMBL. The closest known sequence,  
both at the nucleotide and amino acid levels, is Q9H300. Q9H300 is split into 10 exons, of which  
20 the protein of the invention is missing exon 8, while in AAH03653, it is exon 6 that is absent.

- Pretactilin is a polypeptide that interacts with the carboxyl-terminus of presenilin-1 and  
presenilin-2. Pretactilin harbours six putative transmembrane domains and belongs to the family  
of transmembrane rhomboid like proteins that have been isolated from various organisms, ranging  
from bacteria, plants, invertebrates to humans. The first isolated member of this family, the  
25 *Drosophila melanogaster* Rhomboid protein, is a seven transmembrane domain protein that has  
been implicated in Epidermal Growth Factor Receptor (EGFR) signaling, which as in mammals  
controls many aspects of growth and development. Genetic evidence indicates that Rhomboid  
controls the activation by proteolysis of the transmembrane EGFR ligand, Spitz, a TGF $\alpha$ -like  
molecule presents at the surface of neighbouring cells, to generate an active diffusible form of the  
30 ligand.

- The rhomboid domain of the Pretactilin extends from amino acid positions 186 to 323, and  
includes the predicted transmembrane domain region. It has been recently proposed by Pellegrini  
et al., 2001, J. Alzheimers Dis. 3 (2) which disclosure is hereby incorporated by reference in its  
entirety, that the members of the Rhomboid superfamily possess a metal-dependent protease  
35 activity.

The familial Alzheimer disease gene products, presenilin-1 and presenilin-2, are multipass  
membrane proteins consisting of 6-8 spanning regions that undergo endoproteolytic processing

within their large hydrophilic loop at their carboxyl terminus. Immunolocalization studies have demonstrated that these ubiquitously expressed molecules, primarily located to the endoplasmic reticulum and the golgi apparatus, are also found on nuclear and plasma membranes. The presenilin proteins have been reported to be functionally involved in amyloid precursor protein processing, notch receptor signalling, and programmed cell death, or apoptosis.

Alzheimer's Disease (AD) is a devastating neurodegenerative disorder characterized by progressive memory and cognition impairment associated with an increase secretion and deposition of a 4 kDa beta amyloid peptide (A beta) in extracellular senile plaques in the brain. In both healthy and AD patients, A beta is derived by proteolytic cleavage from the single transmembrane amyloid precursor protein (APP) by various proteinases that have been called APP secretases. Alpha secretases cleave APP within the amyloid sequences, whereas other proteases called beta- and gamma-secretases cleave on the N- and C-terminal ends, respectively. While a transmembrane aspartyl protease, BACE, has been identified as beta-secretase and several proteases may be alpha-secretases (ADAM-10, TACE, PC7), the nature of the gamma-secretase(s) remains elusive. Recently, a number of studies have suggested that the presenilins themselves, missense mutations in which cause the most aggressive forms of familial AD with increased production of A beta, could be the long sought gamma-secretases which release A-beta.

The presenilins family of proteins has also been shown to interact with the Notch signalling pathway by forming stable complexes with Notch and being required for its proper cleavage at the cell surface. Notch is a single transmembrane domain cell surface receptor that mediates many cell fate decisions during development in both vertebrates and invertebrates. Notch is synthesized as a large precursor that is cleaved in the trans-golgi network lumen to generate two fragments that form a heterodimeric receptor at the cell surface. Following ligand receptor binding, the C-terminal transmembrane-intracellular fragment of Notch is cleaved within its transmembrane domain by an as yet unidentified protease. This ligand-activated cleavage releases the Notch intracellular domain from the membrane, allowing it to translocate to the nucleus where it affects the transcriptional activity of target genes through interactions with proteins that include members of the CSL family.

In addition to their roles in APP processing and Notch receptor signaling, extensive evidence suggests that presenilins are also involved in programmed cell death. Over-expression of Presenilin-2 increases apoptosis induced by a number of apoptotic stimuli, whereas mutations in the presenilin genes as found in Familial Alzheimer's Disease cases generate molecules with constitutive pro-apoptotic activity. Complementary studies have demonstrated that depletion of PS2 protein levels by antisense RNA protects cells against apoptosis induced by a number of cell-death-inducing apoptotic stimuli. At the molecular level, it has been observed recently that the carboxyl-termini of presenilin-1 and presenilin-2 interact with Bcl-XL protein, an anti-apoptotic member of the Bcl-2 family, providing an additional link between these proteins and the apoptotic

pathway.

By virtue of its being either a transmembrane protease or a transmembrane protease cofactor, Pretactilin interacts physically with presenilins to form active complexes in the membranes that are involved in APP metabolism, Notch signalling and programmed cell death via specific protein processing. Specifically, Pretactilin contributes to the proteolytic processing of a number of protein substrates including APP and Notch.

In one embodiment of the present invention, Pretactilin can be used in a protease cocktail in order to digest proteins, preferentially transmembrane proteins, from a biological sample. Use of a protease cocktail could be of particular interest either to quickly purify DNA from crude cellular extracts or to remove transmembrane and membrane-associated proteins in isolated membranes preparation in order to prepare protein-free membranes vesicles useful for protein reconstitution and functional assays in vitro. In a preferred embodiment, Pretactilin is added to a protease cocktail in combination with one or more presenilin proteins.

In another embodiment, Pretactilin can be used as a transmembrane marker that would be useful during protein purification methods for monitoring the recovery of transmembrane proteins from a biological sample or from cells grown in vitro. In such methods, the proteins can be detected in any of a number of ways. For example, Pretactilin can be labeled and added to the sample or the cells prior to the purification step. Alternatively, Pretactilin can be recombinantly fused to a detectable protein such as GFP and expressed in the organism from which the sample will be taken, or in the cells, prior to purification. In addition, Pretactilin can be detected throughout the purification steps using a monoclonal or polyclonal antibody that specifically recognizes Pretactilin.

The present invention also provides new methods to purify wild type and mutant presenilin proteins, preferentially human presenilins, consisting in using Pretactilin or fragments thereof to co-immunopurify presenilins from cellular extracts. Methods to co-immunopurify proteins are well known to those skilled in the art. For example, presenilins can be co-immunopurified by affinity column chromatography or by immobilisation on sepharose-beads with monoclonal or a polyclonal antibody that specifically binds Pretactilin. Such purified wild type and mutant presenilins would then be of particular interest to generate presenilin antibodies that could be used for the treatment of Alzheimer's disease. In addition, the purified presenilin polypeptides could subsequently be used for the diagnosis of Alzheimer's disease as described below.

In a further embodiment, the present invention is used in a diagnostic method for detecting Alzheimer's disease in an individual comprising the steps of:

- (a) co-immunopurifying presenilins with Pretactilin from a biological sample,
- (b) adding the corresponding purified polypeptides to membranes vesicles containing a reconstituted presenilins substrate, preferentially the Notch protein, as well as, optionally, a reconstituted Pretactilin,

(c) quantifying protease activity of these membrane vesicles compared to reconstituted positive and negative controls (e.g., identical membrane vesicles where wild type and mutant presenilins have been incorporated, respectively), by proteolytic fragment detection and quantification.

5 In another embodiment, the present invention provides new methods to identify other proteins that interact physically with presenilins and/or Pretactilin. In a preferred method, Pretactilin is used to co-immunopurify presenilin complexes from cellular extracts, preferentially from brain cellular extracts, then disrupting the isolated complexes in order to release its components and identifying the associated proteins, for example by microsequencing followed by  
10 gene cloning and characterisation. Alternatively, Pretactilin can be used as bait in two-hybrid experiments in yeast for the screening of interacting polypeptides. Because such interacting proteins would likely be also involved in the modulation of A beta peptide production, their characterisation would certainly lead to the identification of new genes whose mutations cause or predispose to Alzheimer's disease. They would also provide useful novel targets for gene and drug  
15 therapies of the disease.

In a further embodiment, Pretactilin can be used in a method to locate presenilins in subcellular compartments of a cell, preferentially neuronal cells, comprising the steps of contacting an isolated sample of cells with labeled Pretactilin and detecting the labeling in those cells. Methods used for labeling proteins are well known in the art, any of which can be used in the  
20 present invention.

Pretactilin also provides a method to restore normal APP processing in mutant cells producing increased level of A beta peptide by reducing the level or the activity of the present protein in the cells. This can be achieved using techniques well known in the art, for example using antibodies, antisense molecules, ribozymes, or administering to said mutant cells small  
25 molecule inhibitors of Pretactilin.

The present invention also provides an in vitro system useful to screen for inhibitors of A beta production that could be of particular interest either for the prevention or the treatment of Alzheimer's disease, consisting in transfecting cultured cells in vitro, preferentially brain cells, more preferentially neuronal cells, with a nucleotide sequence encoding Pretactilin placed under  
30 the control of a strong constitutive promoter sequence in order to achieve high expression level of Pretactilin in those cells, applying to the cells the substance to be tested, measuring the amount of A beta peptide produced by these cells compared to control transfected cells.

In another embodiment, Pretactilin can be used to modulate apoptosis of cells. For example, the level of Pretactilin can be increased in cells, preferentially in tumor cells, in vitro or  
35 in vivo, thereby inducing apoptosis. The level or the activity of Pretactilin can be increased in any of a number of ways, including by administering purified Pretactilin to the cells, transfecting the cells with a polynucleotide encoding Pretactilin, or administering a compound to the cells that

causes an increase in the activity or expression of Pretactilin. Alternatively, apoptosis can be inhibited by decreasing the level or the activity of Pretactilin in cells, for example using antibodies, antisense molecules, ribozymes, or small molecule inhibitors of Pretactilin. In a preferred embodiment, Pretactilin is used to inhibit apoptosis of neuronal cells in patients suffering of

5 neurodegenerative diseases, preferentially, Alzheimer's disease.

In another embodiment, the present invention provides a transgenic non-human animal, preferentially a mammal, more preferentially a rodent, producing high level of A beta peptide due to overproduction of Pretactilin. Such transgenic animal would provide a useful in vivo model to study the onset of Alzheimer's disease and more particularly to investigate the role of A beta

10 peptide deposits in the etiology of the disease. It would also be of considerable interest for the screening of compounds that inhibit A beta peptide secretion or accumulation. Such transgenic animal can be obtained by any of the current methods used to generate transgenic animals that are well known for those skilled in the art, for example in the mouse, using DNA microinjection into fertilized eggs or transfection of embryonic stem cells. High over-expression of Pretactilin can be

15 achieved by placing the nucleotide sequence encoding Pretactilin under the control of a strong promoter sequence. The promoter sequence can be derived from a gene having a broad expression in the animal or from a gene whose expression is restricted to the brain. Preferentially, a regulatable promoter sequence is used in order to control temporally the expression of the transgene once introduced into the animal.

20 In another embodiment, the level or the activity of Pretactilin can be modulated to provide a treatment for Alzheimer's disease in a patient. Indeed as A beta peptide deposition is an early and invariant event in Alzheimer's disease, it is believed that a treatment that affects A beta production will be useful in the treatment of the disease. Accordingly, reducing level or activity of Pretactilin in mutant cells would thereby diminish A beta production. This could be achieved by any of the

25 well known strategies used for therapy in vivo, for example using antisense molecules, antibody or small molecule inhibitors of Pretactilin.

**Protein of SEQ ID NO 34: (Internal designation 145606\_106-023-2-0-B3-F):**

The cDNA of clone (SEQ ID NO:33) encodes the human MS4A5 protein, comprising the sequence:

30 MDSSTAHSVPVFLVFPPEITASEYESTELSATTFTSQSPLQKLFARKMKILGTIQILFGIMTFSF  
GVIFLFTLLKPYRPFIFLSGYPFWGSVLFINSAGFLIAVKRKTETLIILSRIMNFLSALGAI  
AGIILLTFGFILDQNYICGYSHQNSQCKAVTVLFLGILITLMTFSIIELFISLPFSILGCHSEDCD  
CEQCC (SEQ ID NO:34). Accordingly, it will be appreciated that all characteristics and uses of  
polypeptides of SEQ ID NO:34 described throughout the present application also pertain to the

35 polypeptides encoded by the nucleic acids included in clone 145606\_106-023-2-0-B3-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:33 described throughout the present application also pertain to the nucleic acids included in

clone 145606\_106-023-2-0-B3-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:33, SEQ ID NO:34, and Clone 145606\_106-023-2-0-B3-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

- 5           The cDNA of SEQ ID NO:33 comprising 5 exons encodes the 200 amino-acid MS4A5 protein (STR Q9H3V2), which belongs to the MS4A protein family (membrane-spanning four-domains, subfamily A). Four members of MS4A family in human (MS4A4-7) and in mouse (MS4A8-11) have been described (Ishibashi K. *et al*, Gene (2001), 264, 87-93 which disclosure is hereby incorporated by reference in its entirety). As with the other members of the
- 10 CD20/Fc(sigma)RI(beta)/HTm4 superfamily, all MS4A proteins are highly hydrophobic with four transmembrane domains (but are distinct from tetraspanin family members which also have four transmembrane domains). The cDNA of SEQ ID NO:33 encoding the protein of SEQ ID NO:34 possesses a conserved sequence around the initiating methionine (ATC ATG G) and a consensus protein kinase A (PKA) phosphorylation site (KRKTT) at the intracellular loop between the second
- 15 and third transmembrane domains. In contrast with other members of MS4A family, which are mostly expressed in lymphoid tissues, MS4A5 is expressed in testis, pancreas, and at low levels in the heart and brain. The gene of MS4A5 is located on human chromosome 11, specifically at position 11q12, the same chromosome as the CD20, Fc(sigma)RI(beta) and HTm4 genes. MS4A5 is a novel transmembrane protein that acts alone or in combination with other proteins as an ion
- 20 channel, e.g. a ligand-gated calcium channel. MS4A5 is involved in a number of cellular functions in non-lymphoid cells, for example intracellular signaling, regulating intracellular calcium concentrations, exocrine functions, and endocrine functions.

- In one embodiment, the protein of the invention or fragment thereof provides a method to detect cells specifically expressing the present protein, using for example flow cytometry
- 25 technology or classical *in situ* detection techniques which are well known in the art. Such methods are useful, e.g. to specifically detect cells of the testis, pancreas, heart, or brain, as the present protein is highly expressed in these cell types. Such methods are also useful to detect cells over- or under-expressing the present protein, and is thus useful for diagnosing diseases or conditions resulting from or associated with an increase or decrease in expression or activity of the protein.
- 30 This method includes the steps of contacting a biological sample obtained from an individual suspected of suffering from the disease or condition, or at risk of developing the disease or condition, with a compound capable of selectively binding the present protein or nucleic acids, e.g. an antibody directed against the present protein or a polynucleotide probe directed against the present cDNA. Following this binding step, the method further comprises detecting the presence
- 35 or absence of selective binding between the compound and the cells or proteins within the sample. In preferred embodiments, the compound is labeled, and the sample comprises cells derived from the testis, pancreas, heart, or brain.

In another embodiment, the protein of the invention or fragment thereof can be used to modulate the proliferation of cells. For example, the level or activity of the present protein can be increased in cells to increase the rate or extent of proliferation of the cells. In one such embodiment, the proliferation of cells in a biological sample is increased by contacting the biological sample with an amount of the present protein sufficient to increase the rate or extent of proliferation of one or more cells within the sample, or with a compound that increases the activity or expression of the present protein within one or more cells of the sample. Such methods can be performed either *in vitro* or *in vivo* and, preferably, the cells comprise pancreatic, testicular, heart or brain cells. The level of the present protein can be increased in cells in any of a number of ways, including by administering purified protein to the cells, transfecting the cells with a polynucleotide encoding the protein, or administering a compound to the cells that causes an increase in the activity or expression of the protein. Alternatively, proliferation of cells can be inhibited by decreasing the level of the present protein in cells, for example using antisense molecules, or more specifically inhibit the activity of the present protein using direct or indirect inhibitor molecules or antagonistic antibodies directed against the present protein.

In a further embodiment, the protein of the invention or fragment thereof can be used to modulate cellular calcium concentration and thereby modulate calcium-dependant signaling. Calcium transport can be modulated, for example, by contacting a biological sample with an amount of the present protein sufficient to increase calcium transport of one or more cells within the sample, or with a compound that increases the activity or expression of the present protein within one or more cells of the sample. Such methods can be used either *in vitro* or *in vivo* and preferably, but not limited to, the methods are performed on cells comprising pancreatic, testicular, heart or brain cells. The level of the present protein can be increased in cells in any of a number of ways, including by administering purified protein to the cells, transfecting the cells with a polynucleotide encoding the protein, or administering a compound to the cells that causes an increase in the activity or expression of the protein. Alternatively, the activity of the present protein can be inhibited by decreasing the level of the present protein in cells, for example using antisense molecules, by using direct or indirect inhibitor molecules or antagonistic antibodies of the present protein, or by expressing in the cells an inactive form of the protein that acts in a dominant negative fashion to inhibit the normal calcium signalling in the cells carried out by other members of the MS4A family.

The present invention also provides animal models generated by modulating the expression or activity of the present protein in one or more tissues of the animal. Such animals represent an *in vivo* assay method for testing candidate molecules potentially useful for the treatment of various pathophysiological aspects of diseases associated with abnormal calcium homeostasis and/or cell growth or any function specifically related to the activity of the present protein. These animals can be generated with any method of increasing or decreasing the expression of the present protein.

In another embodiment, since calcium is an universal intracellular messenger, controlling a diverse range of cellular processes such as gene transcription, cell proliferation, and more specifically muscle contraction, synaptic function, secretion of insulin in pancreatic islets of Langerhans, and many others, the present protein or fragment thereof provides a method of treating  
5 different pathological states arising from or associated with destabilization of calcium homeostasis in many organs (brain, kidney, parathyroid gland, pancreas, bone, intestine). In addition, any of these processes can be enhanced or inhibited in cells or in patients, even when the protein is at normal levels in the cells or in the cells of the patient, by causing a decrease or increase in the normal level of the protein in the cells. For any of the herein-described methods, the activity of the  
10 present protein can be increased or inhibited in any of a large number of ways, for example by using polyclonal or monoclonal antibodies, or any other compound having qualitative biological activity in common with a full-length antibody, that specifically binds to the present protein and exerts stimulatory or inhibitory effects on functions involving the present protein.

Any compound interacting with the present protein and thereby promoting or interfering  
15 with its activities can also be used as a method of treating any of the pathologies described above. Such compounds can be identified, e.g., using interaction-screening approaches such as, but not limited to, co-immunoprecipitation, two-hybrid methods. Further, compounds can be screened for the ability to modulate the activity of the present protein by providing a cell expressing the present protein, or providing lipid bilayers reconstituted with the present protein, and detecting the ability  
20 of a compound to modulate the activity of the present protein in the cell or in the bilayer. Such activity can be detected in any of a large number of ways, including but not limited to detecting calcium flux or calcium signalling in the cells or membranes, e.g. as manifest in the activity of downstream members of the signal transduction pathway. The present invention also provides an *in vitro* method to identify any compound able to promote or interfere with some or all activities of  
25 the present protein, the method comprising the steps of contacting the present protein with a test compound and detecting the ability of the compound to bind to or modulate the activity of the protein. Also in this embodiment, the present protein or any effective compound identified by this way of investigation useful for the treatment of disorders described above can be used in combination with other drugs or compounds.

30 As it has been shown that multiple loci on chromosome 11q13 are relevant to atopic asthma (Adra CN. *et al*, Clin. Genet. (1999) June; 55(6):431-437), the present invention also provides a novel candidate gene for this condition. Accordingly, the present invention provides methods for the diagnosis of atopic asthma, the method comprising determining the identity of one or more nucleotides of the present nucleic acids in one or more cells of an individual suspected of having  
35 the condition, or at risk of developing the condition, and determining if the cell or cell contains a nucleotide within the present nucleic acid sequence indicative of the condition, or of an elevated risk of developing the condition. The identity of such nucleotides can be determined in any of a

number of ways, for example using any standard sequencing or genotyping method, many of which are well known in the art.

**Protein of SEQ ID NO:36 (Internal designation Clone 1000769575\_208-22-1-0-B2-F)**

The cDNA of Clone 1000769575\_208-22-1-0-B2-F (SEQ ID NO:35) encodes the protein  
 5 of SEQ ID NO:36 comprising the amino acid sequence  
 MGMTSSLLKLLKYVLFFFNLLFWICGCCILGFGIYLLIHNNGVLFHNLPSLTGNGVFVIVGSII  
 MVVAFLGCMGSIKENKCLLMSFFILLILLAEVTLAILLFVAKGLTDSIHRYHSDNSTKAA  
 WDSIQSFLQCCGINGTSDWTSGPPASCPDRKVEGCYAKARLWFHSNFFIRGPY.

Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID  
 10 NO:36 described throughout the present application also pertain to the polypeptides encoded by the  
 nucleic acids included in Clone 1000769575\_208-22-1-0-B2-F. In addition, it will be appreciated  
 that all characteristics and uses of the polynucleotides of SEQ ID NO:35 described throughout the  
 present application also pertain to the nucleic acids included in Clone 1000769575\_208-22-1-0-  
 B2-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID  
 15 NO:35, SEQ ID NO:36, and Clone 1000769575\_208-22-1-0-B2-F. Also preferred are polypeptide  
 fragments having a biological activity as described herein and the polynucleotides encoding the  
 fragments.

The protein of SEQ ID NO:36 encodes Antaginin, a complex splice variant of CD53 with  
 novel function. In Antaginin, splicing of exon 4 onto exon 5 results in a deletion of 9 amino acids  
 20 (4 from exon 4, 5 from exon 5) and a correspondingly unique junctional sequence. In addition,  
 splicing of exon 7 onto normally 3'-untranslated nucleotide sequence within exon 8 results in a  
 deletion of 14 amino acids from exon 7, as well as the deletion of the carboxy-terminal 23 amino  
 acids of CD53 and its replacement with a unique carboxy-terminal sequence of 6 amino acids in  
 Antaginin.

25 CD53, restricted in expression to leukocytes, is a member of the tetraspannin superfamily.  
 CD53 is an integral membrane protein characterized by four transmembrane domains (TM1-TM4),  
 forming a small and a large extracellular loop (EC1 and EC2, respectively), with short intracellular  
 amino and carboxyl tails. EC1 and EC2 of CD53 comprise the amino acid sequences 37-54 and  
 107-181, respectively (numbered from the initiating methionine of CD53). TM1-TM4 of CD53  
 30 comprise the amino acid sequences 11-36, 55-69, 81-106, and 182-206, respectively (numbered  
 from the initiating methionine of CD53) (Rost, B. et al., Prot. Sci. 5:1704-18, (1996) which  
 disclosure is hereby incorporated by reference in its entirety).

CD53 facilitates the assembly of modular signalling complexes at the cell surface.  
 Specifically, CD53 acts as an adaptor to functionally link an extracellular ligand-binding domain  
 35 (such as that of beta 1 integrin) to an intracellular domain involved in signal transduction (such as  
 that of protein kinase C) (Zhang, XA et al., J. Biol. Chem. (2001) which disclosure is hereby  
 incorporated by reference in its entirety). Beta 1 integrin has been shown to associate with CD53

through EC2. Moreover, through its interaction with other tetraspaninins, CD53 is incorporated into a higher order tetraspaninin web exisiting at the cell surface. CD53 displays numerous properties that indicate its physiological importance in cell adhesion, motility, activation (including the delivery of a co-stimulatory signal to for CD3/T cell receptor-mediated T cell activation), and proliferation (Boucheix, C. et al. Expert Reviews in Molecular Medicine (2001) which disclosure is hereby incorporated by reference in its entirety).

Antaginin is characterized by a highly perturbed EC2 loop and a highly divergent TM4 transmembrane domain. The EC2/TM4 region of Antaginin comprises amino acids 107-179 (numbered from the initiating methionine of Antaginin). In addition, Antaginin is characterized by an extracellular perturbation of the amino acid sequence at the junction of exons 4 and 5 (amino acids 124/125, numbered from the initiating methionine of Antaginin) (Rost, B. et al., Prot. Sci. 5:1704-18, (1996) which disclosure is hereby incorporated by reference in its entirety). Antaginin antagonizes CD53-facilitated assembly of functional modular signalling complexes at the cell surface.

In a preferred embodiment, the present invention provides for an antibody that specifically binds Anataginin of the present invention. Further preferred is a method for making such antibody wherein a mouse is immunized with a syngeneic cell line transfected with Antaginin. Monoclonal antibodies derived from said mouse are screened for binding to the Antaginin-transfected cell line but not to the identical cell line transfected with human CD53. Antibody specificity is further established through amino acid sequence analysis of immunoprecipitated material. Further preferred is a method for making said antibody wherein said antibody binds to EC1 or the sequence carboxyl-terminal (EC2/TM-4 region) of Antaginin. EC1 and the EC2/TM4 region of Antaginin comprise the amino acid sequences 37-54 and 107-179, respectively (numbered from the initiating methionine of Antaginin). Further preferred is a method for making said antibody wherein said antibody binds to the EC2/TM4 region of Antaginin. Methods of generating said monoclonal antibody and of establishing its specificity are well known to those skilled in the art.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Antaginin. Further preferred is a method for using said antibody diagnostically to determine the basis for an impaired immune response. Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Antaginin expression by leukocytes in a pathological context. Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Antaginin expression by leukocytes in the context of viral infection wherein the virus is selected from, but not restricted to, the group consisting of: (a) Cytomegalovirus; (b) Human immunodeficiency virus; (c) Human herpes virus 6 (HHV 6); (d) Hepatitis C virus; and (e) Hepatitis D virus.

Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Antaginin expression by normal leukocytes in the leukemic patient to determine the

basis for an impaired anti-tumor immune response wherein the leukemia is selected from, but not restricted to, the group consisting of: (a) B cell acute lymphoblastic leukemia (B-ALL); (b) Chronic lymphocytic leukemia (CLL); (c) T cell acute lymphoblastic leukemia (T-ALL); (d) Multiple myeloma; and (e) Acute myeloid leukemia (AML).

- 5 Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Antaginin expression by normal leukocytes in the cancer patient to determine the basis for an impaired anti-tumor immune response wherein the cancer is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Hodgkin's lymphoma; (f) Non-Hodgkin's lymphoma; (g) Prostatic carcinoma;
- 10 (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

- The threshold for leukocyte activation can be regulated by cytokine. In a further embodiment, the present invention provides for the use of said Antaginin antibody in in vitro analysis of cytokine regulation of Antaginin expression by leukocytes. Further preferred is a
- 15 method of using said antibody in a flow cytometric analysis of said regulation by cytokine wherein the cytokine is selected from, but not restricted to, the group consisting of: (a) Interferon gamma; (b) Interleukin 17; (c) Interleukin 4; (d) Interleukin 10; (e) Interleukin 13; (f) Interleukin 15; (g) Interleukin 1; (h) Interleukin 6; (i) Monocyte chemotactic protein 1 (MCP-1); (j) Interleukin 8; and (k) Tumor necrosis factor alpha.

- 20 Further preferred is a method of contacting said antibody with Antaginin and thereby sterically inhibiting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signalling complexes at the cell surface. In so doing, said Antaginin antibody up-regulates CD53-mediated leukocyte activation. Preferred compositions comprise the Antaginin antibody or fragments or derivatives thereof. Preferred route of administration is intravenous
- 25 injection.

- In a further embodiment of the invention, said Antaginin antibody is incorporated as an adjuvant in vaccine preparations in a method to up-regulate the elicited immune response. In said method, said Antaginin antibody facilitates the CD53-mediated leukocyte activation contributing to establishment of specific immunity. Said Antaginin antibody up-regulates CD53-mediated
- 30 leukocyte activation by sterically inhibiting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signaling complexes at the cell surface. Further preferred is a method to use said antibody in a vaccine targeting a viral infection wherein the virus is selected from, but not restricted to, the group consisting of: (a) Human immunodeficiency virus; (b) Human herpes virus 6 (HHV 6); (c) Hepatitis C virus; (d) Hepatitis D virus; (e) Hepatitis E
- 35 virus; (f) Cytomegalovirus; (g) Respiratory syncytial virus; (h) Herpes simplex virus type I; (i) Herpes simplex virus type II; (j) Influenza virus; (k) Parvovirus; (l) Coxsackie virus; (m) Echovirus; (n) Epstein-Barr virus; (o) Dengue virus; (p) Lassa fever virus; and (q) Ebola virus.

Further preferred is a method to use said Antaginin antibody in a vaccine targeting a protozoan infection wherein the protozoa is selected from, but not restricted to, the group consisting of: (a) *Entamoeba histolytica*; (b) *Cryptosporidium parvum*; (c) *Plasmodium falciparum*; (d) *Trypanosoma*; (e) *Leishmania*; (f) *Trichomonas vaginalis*; and (g) *Acanthamoeba*.

- 5 Viruses can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Antaginin antibody is used in a method of up-regulating the immune response against an ongoing viral infection. In said method, said Antaginin antibody facilitates the CD53-mediated leukocyte activation contributing to the anti-viral immune response. Said Antaginin antibody up-regulates CD53-mediated leukocyte activation by sterically
- 10 inhibiting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signaling complexes at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing viral infection wherein the virus is selected from, but not restricted to, the group consisting of: (a) Human immunodeficiency virus; (b) Human herpes virus 6 (HHV 6); (c) Hepatitis B virus; (d) Hepatitis C virus; (e) Hepatitis D virus; (f) Cytomegalovirus;
- 15 (g) Respiratory syncytial virus; (h) Influenza virus; (i) Herpes simplex virus type I; (j) Herpes simplex virus type II; (k) Epstein Barr virus; (l) Varicella zoster virus; (m) Morbillivirus; (n) Paramyxovirus; (o) Papilloma virus; (p) Adenovirus; (q) Dengue virus; (r) Lassa fever virus; (s) Coxsackie virus; (t) Echovirus; and (u) Ebola virus.

Bacteria can suppress the immune response as a means of evading immune surveillance.

- 20 In a further embodiment of the invention, said Antaginin antibody is used in a method of up-regulating the immune response against an ongoing bacterial infection. In said method, said Antaginin antibody facilitates the CD53-mediated leukocyte activation contributing to the anti-bacterial immune response. Said Antaginin antibody up-regulates CD53-mediated leukocyte activation by sterically inhibiting the capacity of Antaginin to antagonize the CD53-facilitated
- 25 assembly of functional modular signaling complexes at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing bacterial infection wherein the bacteria is selected from, but not restricted to, the group consisting of: (a) *Mycobacterium avium* complex; (b) *Pneumocystis carinii*; (c) *Acne vulgaris*; (d) *Legionella pneumophila*; (e) *Yersinia pestis*; (f) *Ureaplasma urealyticum*; (g) *Chlamydia pneumoniae*; (h) *Helicobacter pylori*;
- 30 (i) *Treponema pallidum*; (j) *Neisseria gonorrhoeae*; (k) *Salmonella typhimurium*; (l) *Vibrio cholera*; (m) *Clostridium difficile*; (n) Bacillary dysentery; (o) Penicillin resistant *Pneumococcus*; (p) *Burkholderia mallei*; (q) *Mycobacterium leprae*; (r) *Mycobacterium haemophilum*; (s) *Mycobacterium kansasii*; (t) *Haemophilus influenzae*; and (u) *Bacillus anthracis*.

Protozoa can suppress the immune response as a means of evading immune surveillance.

- 35 In a further embodiment of the invention, said Antaginin antibody is used in a method of up-regulating the immune response against an ongoing protozoan infection. In said method, said Antaginin antibody facilitates the CD53-mediated leukocyte activation contributing to the anti-

protozoan immune response. Said Antaginin antibody up-regulates CD53-mediated leukocyte activation by sterically inhibiting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signaling complexes at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing protozoan infection wherein the

5 protozoa is selected from, but not restricted to, the group consisting of: (a) *Entamoeba histolytica*; (b) *Cryptosporidium parvum* (c) *Giardia lamblia*; (d) *Toxoplasma gondii*; (e) *Isospora belli*; (f) *Encephalitozoon cuniculi*; (g) *Enterocytozoon bieneusi*; (h) *Plasmodium falciparum*; (i) *Trypanosoma*; (j) *Leishmania*; (k) *Trichomonas vaginalis*; and (l) *Acanthamoeba*.

In a further embodiment of the invention, said Antaginin antibody is used in a method of

10 up-regulating the immune response against an ongoing fungal infection wherein the fungus is selected from, but not restricted to, the group consisting of: (a) *Cryptococcal meningitis*; (b) *Histoplasma capsulatum*; (c) *Coccidioides immitis*; and (d) *Candida albicans*.

Tumors can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Antaginin antibody is used in a method of up-

15 regulating the immune response against a tumor. In said method, said Antaginin antibody facilitates the CD53-mediated leukocyte activation contributing to the anti-tumor immune response. Said Antaginin antibody up-regulates CD53-mediated leukocyte activation by sterically inhibiting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signaling complexes at the cell surface. Further preferred is a method of up-regulating the

20 immune response against a tumor wherein the tumor is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Hodgkin's lymphoma; (f) Non-Hodgkin's lymphoma; (g) Prostatic carcinoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

25 In a further embodiment of the invention, said Antaginin antibody is incorporated as an adjuvant in therapeutic anti-tumor vaccines wherein the tumor is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Hodgkin's lymphoma; (f) Non-Hodgkin's lymphoma; (g) Prostatic carcinoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma;

30 (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

Intracellular (macrophage) pathogens can be eliminated either through macrophage activation or through lysis of infected macrophages by cytolytic T lymphocytes (Chun et al., J. Exp. Med. 193:1213 (2001) which disclosure is hereby incorporated by reference in its entirety). In a further embodiment of the invention, said Antaginin antibody is used in a method to eliminate

35 intracellular pathogens by facilitating macrophage activation or cytolytic T lymphocyte generation wherein the pathogen is selected from, but not restricted to, the group of intracellular (macrophage) pathogens consisting of: (a) *Histoplasma capsulatum*; (b) *Mycobacterium tuberculosis*;

(c) *Salmonella typhimurium*; (d) *Chlamydia trachomatis*; and (e) *Pneumocystis carinii*.

There have been several examples of tetraspanins playing a role in the viral life cycle. Anti-tetraspanin antibodies inhibit syncytium formation and/or virus production. This was observed for the tetraspanins CD81 and CD82 with human T-lymphotropic virus 1, and for the tetraspanin CD9 with the feline immunodeficiency virus and the canine distemper virus. It is also believed that the tetraspanin CD81 also plays a role in the aetiopathogenesis of hepatitis C virus (Boucheix, C. et al. (2001) which disclosure is hereby incorporated by reference in its entirety). In a further embodiment of the invention, said Antaginin antibody is used in a method of blocking viral infection when Antaginin is used as a virus receptor. Further preferred is the use of said Antaginin antibody in a method of blocking said viral infection when Antaginin used as said virus receptor and is expressed by a leukocyte type selected from, but not restricted to, the group of leukocyte types consisting of: (a) T lymphocyte; (b) B lymphocyte; (c) NK lymphocyte; (d) Monocyte; (e) Macrophage; (f) Neutrophil; and (g) Dendritic cell.

In a further preferred embodiment, the present invention provides for a method of screening test compounds for the ability to bind Antaginin and either inhibit or promote the capacity of Antaginin to interfere with CD53 function. Further preferred is a method of screening said test compounds for the ability to bind Antaginin and either inhibit or promote the capacity of Antaginin to interfere with CD53 function as it relates its facilitation of signal transduction through beta 1 integrin (Zhang, XA et al., J. Biol. Chem. (2001) which disclosure is hereby incorporated by reference in its entirety). Further preferred is a method of screening said test compounds for the ability to bind Antaginin and either inhibit or promote the capacity of Antaginin to interfere with the CD53-facilitated association of protein kinase C with beta 1 integrin. Further preferred is a method of screening said test compounds for the ability to bind Antaginin and either inhibit or promote the association of protein kinase C with beta 1 integrin in a beta 1 (alpha3beta1, alpha4beta1, or alpha6beta1)-expressing cell line transfected with CD53 and Antaginin but not in the identical cell line transfected with CD53 alone. Methods of screening said test compounds and for characterizing their effect on CD53-facilitated association of protein kinase C with beta 1 integrin are well known to those skilled in the art.

Preferred formulation of said compound is that selected from, but not restricted to, formulations compatible with the routes of delivery selected from the group: (a) Oral; (b) Transdermal; (c) Injection; (d) Buccal; and (d) Aerosol.

Compounds found to bind Antaginin and to inhibit the capacity of Antaginin to interfere with CD53 function, thereby effectively up-regulating CD53 activity, are used in methods analogous to those described above for Antaginin antibody.

Compounds found to bind Antaginin and to promote the capacity of Antaginin to interfere with CD53 function effectively down-regulate CD53 activity. Such compounds have application to chronic inflammatory autoimmune disease and to other disorders of immune dysregulation.

Such compounds down-regulate CD53-mediated leukocyte activation by promoting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signaling complexes at the cell surface. In a further embodiment of the invention, said compound is used in a method of contacting Antaginin to down-regulate a dysregulated immune response and thereby treat the

- 5 associated immune disorder wherein said immune disorder is selected from, but not restricted to, the group: (a) Rheumatoid arthritis; (b) Inflammatory bowel disease; (c) Insulin dependent diabetes mellitus (Type 1 diabetes); (d) Multiple sclerosis; (e) Systemic lupus erythematosus; (f) Psoriasis; (g) Allergic asthma; (h) Allergic rhinitis (hayfever); and (i) Graft versus host disease.

- In a further embodiment of the invention, said test compound having the ability to promote the  
10 capacity of Antaginin to interfere with CD53 function is used in a method to suppress acute inflammation. Said test compounds down-regulate CD53-mediated leukocyte activation by promoting the capacity of Antaginin to antagonize the CD53-facilitated assembly of functional modular signalling complexes at the cell surface. Further preferred is a method to use said test compound to suppress inflammation associated with wound healing. Further preferred are  
15 compositions comprised of said test compound used in methods of contacting a wound or injured tissue with an ameliorative effective amount by injection or transdermal contact at the site of the wound.

**Protein of SEQ ID NO:38 (Internal designation Clone 146994\_106-023-4-0-C9-F)**

- The cDNA of Clone 146994\_106-023-4-0-C9-F (SEQ ID NO:37) encodes the protein of  
20 SEQ ID NO:38 comprising the amino acid sequence:  
MSPGQPMTFPPEALWVTVGLSVCLIALLVALAFVCWRKIKQSCEEENAGAEDQDGEGEKS  
KTALQPLKHSDSKEDDGQEIA. Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:38 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 146994\_106-023-4-0-C9-F. In  
25 addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:37 described throughout the present application also pertain to the nucleic acids included in Clone 146994\_106-023-4-0-C9-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:37, SEQ ID NO:38, and Clone 146994\_106-023-4-0-C9-F. Also preferred are polypeptide fragments having a biological activity as described herein and the  
30 polynucleotides encoding the fragments.

The protein of SEQ ID NO:38 encodes Beferin. Beferin is a novel splice variant of two recently described members of the B lymphocyte activation antigen B7 (BLAA) family, B7-H3 and Blaa. Beferin has novel function as described below.

- B7-H3 was identified as a human B7-like molecule with T lymphocyte costimulatory  
35 activity (Chapoval, AI et al., Nature Immunology 2:269-74 (2001) which disclosure is hereby incorporated by reference in its entirety). B7-H3 has the structure:

[Signal peptide]-[IgV-like domain 1]-[IgC-like domain 2]-[transmembrane region]-

[cytoplasmic tail].

Blaa (NCBI Accession No. AX097550) was identified as a human B7-like molecule, as described in Patent Application WO00118204A1 ("Polynucleotides encoding members of the human B lymphocyte activation antigen B7 family and polypeptides encoded thereby") and incorporated by reference in its entirety. Blaa has the structure:

[Signal peptide]-[IgV-like domain 1]-[IgC-like domain 1]-[IgV-like domain 2]-[IgC-like domain 2]-[transmembrane region]-[cytoplasmic tail].

Blaa (NCBI Accession No. AX047070) was independently identified as a protein with beta-secretase (beta-amyloid-converting enzyme) activity, as described in Patent Application WO00068266A1 ("Amyloid precursor protein protease and related nucleic acid compositions") and incorporated by reference in its entirety. The amino acid sequence of AX947070 is identical to that of AX097550.

IgV-like domain 1 is highly similar, but not identical, to the amino acid sequence of IgV-like domain 2. IgC-like domain 1 is highly similar, but not identical, to the amino acid sequence of IgC-like domain 2.

In the case of Beferin, a novel 5' exon is spliced directly onto the exons encoding the transmembrane region and cytoplasmic tail. This results in the deletion of the IgV-like and IgC-like extracellular domains. The short extracellular tail of Beferin is comprised of approximately seven amino acids shared with B7-H3 and Blaa preceded by three novel (not found in either B7-H3 or Blaa) N-terminal amino acids encoded by the novel 5' exon (underlined here): MSPGQPMTFP.

Costimulation, in addition to T cell receptor engagement, is required for optimal activation of T cells. The most extensively studied costimulatory molecules are members of the B lymphocyte activation antigen B7 family, of which there are presently five. Each B7 family member binds to one or more counter-receptor on the T cell, of which there are presently four. B7-H3 is highly expressed in many human tissues including heart, liver, placenta, prostate, testis, uterus, pancreas, small intestine, and colon. Low expression of B7-H3 was also found in brain, skeletal muscle, kidney, and lung. B7-H3 is not detectable in peripheral blood mononuclear cells, although it can be induced on dendritic cells and monocytes by inflammatory cytokines. Several tumor lines also express B7-H3, including those derived from melanoma, cervical adenocarcinoma, chronic myelogenous leukemia, lung carcinoma, and colorectal adenocarcinoma. B7-H3 costimulates proliferation of both CD4<sup>+</sup> and CD8<sup>+</sup> T cells, enhances the induction of cytotoxic T lymphocytes (CTL), and selectively stimulates proinflammatory cytokine interferon gamma (IFN<sub>gamma</sub>) production in the presence of T cell receptor signaling. B7-H3 exists as non-covalent oligomers on the antigen-presenting cell, and this is important for high-avidity binding of B7-H3 to its counter-receptor in its role as T cell costimulator.

In non-neuronal tissue, Blaa cleaves the 751 amino acid isoform of amyloid beta protein precursor (APP751) at the cell surface by virtue of its beta-secretase activity to generate a soluble

fragment identical to the serine protease inhibitor protease nexin 2 (PN2). PN2 and its Kunitz protease inhibitory domain have been shown to be inhibitors of coagulation factor VIIa (FVIIa) and factor VIIa-tissue factor complex (FVIIa-TF) (Mahdi, F et al., Thromb. Res. 99:267-76 (2000) which disclosure is hereby incorporated by reference in its entirety) initiators of the extrinsic  
5 coagulation cascade. TF expression and its engagement of the extrinsic coagulation pathway by ovarian cancer cells has been shown to play role in metastasis of the cancer (Fischer, EG et al., J. Clin. Invest. 104:1213-21 (1999) which disclosure is hereby incorporated by reference in its entirety). Factor Xa (FXa) generated by FVIIa-TF has been shown to lead to pro-inflammatory activation of vascular endothelial cells through its cleavage of protease-activated receptor 2  
10 (PAR2) (Camerer, E et al., Proc. Natl. Acad. Sci. USA 97:5255-60 (2000) which disclosure is hereby incorporated by reference in its entirety). FXa can also elicit a pro-inflammatory cellular response by cleavage of protease-activated receptor 1 (PAR1) (Kravchenko, RM Blood 97:3109-16 (2001) which disclosure is hereby incorporated by reference in its entirety).

Beferin interferes with B7-H3 co-stimulation of T lymphocytes through its non-productive  
15 incorporation into B7-H3 oligomers at the cell surface. One function of Beferin therefore is to negatively regulate T lymphocyte co-stimulation. In a pathological context, Beferin up-regulation facilitates evasion of immune surveillance by pathogens and tumor cells.

Beferin interferes with Blaa generation of PN2 through its non-productive interactions with APP751. A second functional consequence of Beferin expression is therefore up-regulated  
20 engagement of the extrinsic coagulation pathway, including the generation of FXa. In a pathological context, Beferin up-regulation facilitates hypercoagulability and cancer metastasis.

In a preferred embodiment, the present invention provides for an antibody that specifically binds Beferin of the present invention. Further preferred is a method for making such antibody wherein a mouse is immunized with a syngeneic cell line transfected with Beferin. Monoclonal  
25 antibodies derived from said mouse are screened for binding to the Beferin-transfected cell line but not to the identical cell line transfected with human B7-H3 or Blaa. Antibody specificity is further established through amino acid sequence analysis of immunoprecipitated material. Further preferred is a method for making said antibody wherein said antibody specifically binds all or in part to the extracellular amino terminus of Beferin. The extracellular amino terminus of Beferin is  
30 comprises the amino acid sequence 1-10 (numbered from the initiating methionine of Beferin). Methods of generating said monoclonal antibody and of establishing its specificity are well known to those skilled in the art.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Beferin. Further preferred is a method for using said  
35 antibody diagnostically to determine the basis for an impaired immune response or for hypercoagulability. Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Beferin expression by leukocytes in a pathological context. Further

preferred is a method of using said antibody diagnostically in an immunohistochemical analysis of Beferin expression by tissue in a pathological context. Methods of carrying out immunohistochemical or flow cytometric analysis are well known to those skilled in the art.

Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Beferin expression by normal leukocytes and leukemia cells in the leukemic patient to determine the basis either for an impaired anti-tumor immune response or for hypercoagulability wherein the leukemia is selected from, but not restricted to, the group consisting of: (a) B cell acute lymphoblastic leukemia (B-ALL); (b) Chronic lymphocytic leukemia (CLL); (c) T cell acute lymphoblastic leukemia (T-ALL); (d) Multiple myeloma; and (f) Acute myeloid leukemia (AML).

Further preferred is a method of using said antibody diagnostically in a flow cytometric analysis of Beferin expression by leukocytes in a patient with viral infection to determine the basis either for an impaired anti-viral immune response or for hypercoagulability wherein the virus is selected from, but not restricted to, the group consisting of: (a) Cytomegalovirus; (b) Human herpes virus 6 (HHV 6); (c) Human immunodeficiency virus; (d) Hepatitis C virus; and (e) Hepatitis D virus.

Further preferred is a method of using said antibody diagnostically in an immunohistochemical analysis of Beferin expression by tissue to determine the basis for hypercoagulability wherein said tissue is selected from, but not restricted to, the group consisting of: (a) Heart; (b) Liver; (c) Placenta; (d) Prostate; (e) Testis; (f) Uterus; (g) Pancreas; (h) Small intestine; (i) Colon; (j) Kidney; and (k) Lung.

Further preferred is a method of using said antibody diagnostically in an immunohistochemical analysis of Beferin expression by tumor cells to determine the basis either for an impaired anti-tumor immune response or for hypercoagulability wherein the tumor cell is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Hodgkin's lymphoma; (f) Non-Hodgkin's lymphoma; (g) Prostatic carcinoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

The efficiency of T lymphocyte co-stimulation, as well as coagulability status, can be regulated by cytokine. In a further embodiment, the present invention provides for the use of said Beferin antibody in in vitro analysis of cytokine regulation of Beferin expression by normal leukocytes. Further preferred is a method of using said antibody in a flow cytometric analysis of said regulation by cytokine wherein the cytokine is selected from, but not restricted to, the group consisting of: (a) Interferon gamma; (b) Interleukin 17; (c) Interleukin 4; (d) Interleukin 10; (e) Interleukin 13; (f) Interleukin 15; (g) Interleukin 1; (h) Interleukin 6; (i) Monocyte chemotactic protein 1 (MCP-1); (j) Vascular endothelial growth factor (VEGF); (k) Transforming growth factor beta; (l) Interleukin 8; and (m) Tumor necrosis factor alpha.

In a further embodiment, the present invention provides for the use of said Beferin antibody in in vitro analysis of cytokine regulation of Beferin expression by non-leukocytic cell lines. Further preferred is a method of using said antibody in a flow cytometric analysis of said regulation by cytokine wherein the cytokine is selected from, but not restricted to, the group consisting of: (a) Interferon gamma; (b) Interleukin 17; (c) Interleukin 4; (d) Interleukin 10; (e) Interleukin 13; (f) Interleukin 15; (g) Interleukin 1; (h) Interleukin 6; (i) Monocyte chemotactic protein 1 (MCP-1); (j) Vascular endothelial growth factor (VEGF); (k) Transforming growth factor beta; (l) Interleukin 8; and (m) Tumor necrosis factor alpha.

Further preferred is a method of contacting and specifically binding said antibody with Beferin and thereby sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. In so doing, said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation. Further preferred is a method of contacting and specifically binding said antibody with Beferin and thereby sterically interfering with the non-productive interaction of Beferin with APP751, thereby un-regulating Bla-a-mediated beta secretase cleavage of APP751 to generate PN2. As PN2 is an inhibitor of the extrinsic coagulation pathway at the level of FVIIa-TF, this in turn down-regulates coagulability status. Preferred compositions comprise the Beferin antibody or fragments or derivatives thereof. Preferred route of administration is intravenous injection.

In a further embodiment of the invention, said Beferin antibody is incorporated as an adjuvant in vaccine preparations in a method to up-regulate the elicited immune response. In said method, said Beferin antibody facilitates the B7-H3-mediated T lymphocyte co-stimulation contributing to establishment of specific immunity. Said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation by sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. Further preferred is a method to use said antibody in a vaccine targeting a viral infection wherein the virus is selected from, but not restricted to, the group consisting of: (a) Human immunodeficiency virus; (b) Human herpes virus 6 (HHV 6); (c) Hepatitis C virus; (d) Hepatitis D virus; (e) Hepatitis E virus; (f) Cytomegalovirus; (g) Respiratory syncytial virus; (h) Herpes simplex virus type I; (i) Herpes simplex virus type II; (j) Influenza virus; (k) Parvovirus; (m) Coxsackie virus; (n) Echovirus; (o) Epstein-Barr virus; (p) Dengue virus; (q) Lassa fever virus; and (r) Ebola virus.

Further preferred is a method to use said Beferin antibody in a vaccine targeting a protozoan infection wherein the protozoa is selected from, but not restricted to, the group consisting of: (a) Entamoeba histolytica; (b) Cryptosporidium parvum; (c) Plasmodium falciparum; (d) Trypanosoma; (e) Leishmania; (f) Trichomonas vaginalis; and (g) Acanthamoeba. Viruses can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Beferin antibody is used in a method of up-regulating the immune response against an ongoing viral infection. In said method, said Beferin antibody

facilitates the B7-H3-mediated T lymphocyte co-stimulation contributing to the anti-viral immune response. Said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation by sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing

5 viral infection wherein the virus is selected from, but not restricted to, the group consisting of:

(a) Human immunodeficiency virus; (b) Human herpes virus 6 (HHV 6); (c) Hepatitis B virus; (d) Hepatitis C virus; (e) Hepatitis D virus; (f) Cytomegalovirus; (g) Respiratory syncytial virus; (h) Influenza virus; (i) Herpes simplex virus type I; (j) Herpes simplex virus type II; (k) Epstein Barr virus; (l) Varicella zoster virus; (m) Morbillivirus; (n) Paramyxovirus; (o) Papilloma virus;

10 (p) Adenovirus; (q) Dengue virus; (r) Lassa fever virus; (s) Coxsackie virus; (t) Echovirus; and (u) Ebola virus.

Bacteria can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Beferin antibody is used in a method of up-regulating the immune response against an ongoing bacterial infection. In said method, said

15 Beferin antibody facilitates the B7-H3-mediated T lymphocyte co-stimulation contributing to the anti-bacterial immune response. Said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation by sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing bacterial infection wherein the bacteria is selected from, but not

20 restricted to, the group consisting of: (a) Mycobacterium avium complex; (b) Pneumocystis carinii; (c) Acne vulgaris; (d) Legionella pneumophila; (e) Yersinia pestis; (f) Ureaplasma urealyticum; (g) Chlamydia pneumoniae; (h) Helicobacter pylori; (i) Treponema pallidum; (j) Neisseria gonorrhoeae; (k) Salmonella typhimurium; (l) Vibrio cholera; (m) Clostridium difficile; (n) Bacillary dysentery; (o) Penicillin resistant Pneumococcus; (p) Burkholderia mallei;

25 (q) Mycobacterium leprae; (r) Mycobacterium haemophilum; (s) Mycobacterium kansasii; (t) Haemophilus influenzae; and (u) Bacillus anthracis.

Protozoa can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Beferin antibody is used in a method of up-regulating the immune response against an ongoing protozoan infection. In said method, said

30 Beferin antibody facilitates the B7-H3-mediated T lymphocyte co-stimulation contributing to the anti-protozoan immune response. Said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation by sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. Further preferred is a method of up-regulating the immune response against an ongoing protozoan infection wherein the protozoa is selected from, but not

35 restricted to, the group consisting of: (a) Entamoeba histolytica; (b) Cryptosporidium parvum (c) Giardia lamblia; (d) Toxoplasma gondii; (e) Isospora belli; (f) Encephalitozoon cuniculi; (g) Enterocytozoon bieneusi; (h) Plasmodium falciparum; (i) Trypanosoma; (j) Leishmania;

(k) *Trichomonas vaginalis*; and (l) *Acanthamoeba*.

In a further embodiment of the invention, said Beferin antibody is used in a method of up-regulating the immune response against an ongoing fungal infection wherein the fungus is selected from, but not restricted to, the group consisting of: (a) *Cryptococcal meningitis*; (b) *Histoplasma capsulatum*; (c) *Coccidioides immitis*; and (d) *Candida albicans*.

Tumors can suppress the immune response as a means of evading immune surveillance. In a further embodiment of the invention, said Beferin antibody is used in a method of up-regulating the immune response against a tumor. In said method, said Beferin antibody facilitates the B7-H3-mediated T lymphocyte co-stimulation contributing to the anti-tumor immune response. Said Beferin antibody up-regulates B7-H3-mediated T lymphocyte co-stimulation by sterically inhibiting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. Further preferred is a method of up-regulating the immune response against a tumor wherein the tumor is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Prostatic carcinoma; (f) Hodgkin's lymphoma; (g) Non-Hodgkin's lymphoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

In a further embodiment of the invention, said Beferin antibody is incorporated as an adjuvant in therapeutic anti-tumor vaccines wherein the tumor is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Prostatic carcinoma; (f) Pancreatic carcinoma; (g) Uterine carcinoma; (h) Ovarian carcinoma; (i) Testicular carcinoma; (j) Renal carcinoma; (k) Hepatic carcinoma; and (l) Lung non-small-cell carcinoma.

Intracellular (macrophage) pathogens can be eliminated either through macrophage activation or through lysis of infected macrophages by cytolytic T lymphocytes (Chun et al., J. Exp. Med. 193:1213 (2001) which disclosure is hereby incorporated by reference in its entirety). Ligation of B7 family members expressed on the macrophage can lead to macrophage activation [Hirokawa, M Immunol. Lett. 50:95-8 (1996), which disclosure is hereby incorporated by reference in its entirety]. In a further embodiment of the invention, said Beferin antibody is used in a method to eliminate intracellular pathogens by facilitating macrophage activation or cytolytic T lymphocyte generation wherein the pathogen is selected from, but not restricted to, the group of intracellular (macrophage) pathogens consisting of: (a) *Histoplasma capsulatum*; (b) *Mycobacterium tuberculosis*; (c) *Salmonella typhimurium*; (d) *Chlamydia trachomatis*; and (e) *Pneumocystis carinii*.

Tumors can engage the extrinsic coagulation pathway through TF expression as a means of facilitating metastasis. In a further embodiment of the invention, said Beferin antibody is used in a method of down-regulating said tumor engagement of the extrinsic coagulation pathway. In said

method, said Beferin antibody facilitates Bla-a-mediated beta secretase cleavage of APP751 to generate PN2, which is an inhibitor of the extrinsic coagulation pathway at the level of FVIIa-TF. Said Beferin antibody facilitates Bla-a-mediated generation of PN2 by sterically interfering with the non-productive interaction of Beferin with APP751. Further preferred is a method of down-regulating tumor engagement of the extrinsic coagulation pathway wherein the tumor is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Prostatic carcinoma; (f) Hodgkin's lymphoma; (g) Non-Hodgkin's lymphoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

In a further preferred embodiment, the present invention provides for a method of screening test compounds for the ability to bind Beferin and either inhibit or promote the capacity of Beferin to interfere with B7-H3 function. Further preferred is a method of screening said test compounds for the ability to bind Beferin and either inhibit or promote the capacity of Beferin to interfere with B7-H3-mediated T lymphocyte co-stimulation. Further preferred is a method of screening said test compounds for the ability to bind Beferin and either inhibit or promote B7-H3-mediated T lymphocyte co-stimulation when the antigen-presenting cell is transfected with B7-H3 and Beferin but not when the identical cell is transfected with B7-H3 alone. Methods of screening said test compounds and for characterizing their effect on B7-H3-mediated T lymphocyte co-stimulation are well known to those skilled in the art.

Preferred formulation of said compound is that selected from, but not restricted to, formulations compatible with the routes of delivery selected from the group: (a) Oral; (b) Transdermal; (c) Injection; (d) Buccal; and (e) Aerosol.

Compounds found to bind Beferin and to inhibit the capacity of Beferin to interfere with B7-H3 function, thereby effectively up-regulating B7-H3 activity, are used in methods analogous to those described above for Beferin antibody.

Compounds found to bind Beferin and to promote the capacity of Beferin to interfere with B7-H3-mediated T lymphocyte co-stimulation effectively down-regulate B7-H3 activity. Such compounds have application to chronic inflammatory autoimmune disease and to other disorders of immune dysregulation. Such compounds down-regulate B7-H3-mediated T lymphocyte co-stimulation by promoting the non-productive incorporation of Beferin into B7-H3 oligomers at the cell surface. In a further embodiment of the invention, said compound is used in a method of contacting Beferin to down-regulate a dysregulated immune response and thereby treat the associated immune disorder wherein said immune disorder is selected from, but not restricted to, the group: (a) Rheumatoid arthritis; (b) Inflammatory bowel disease; (c) Insulin dependent

diabetes mellitus (Type 1 diabetes); (d) Multiple sclerosis; (e) Systemic lupus erythematosus; (f) Psoriasis; (g) Allergic asthma; (h) Allergic rhinitis (hayfever); and (i) Graft versus host disease.

In a further preferred embodiment, the present invention provides for a method of screening test compounds for the ability to bind Beferin and inhibit the capacity of Beferin to interfere with Blaa function. Further preferred is a method of screening said test compounds for the ability to bind Beferin and up-regulate Blaa-mediated PN2 generation through APP751 cleavage, thereby down-regulating engagement of the extrinsic coagulation pathway by virtue of PN2 being an inhibitor of said pathway. Further preferred is a method of screening said test compounds for the ability to bind Beferin and up-regulate Blaa-mediated PN2 generation by interfering with the non-productive interaction of Beferin with APP751. Further preferred is a method of screening said test compounds for the ability to bind Beferin and up-regulate PN2 release from an APP751-expressing cell transfected with Beferin and Blaa but not from the identical cell line transfected with Blaa alone. Methods of screening said test compounds and for measuring the amount PN2 released into the culture medium are well known to those skilled in the art.

Said compounds found to bind Beferin and to effect said down-regulation of the extrinsic coagulation pathway are used in methods in methods analogous to those described above for Beferin antibody.

**Protein of SEQ ID NO:40 (Internal designation Clone 1000838788\_228-28-4-0-F7-F)**

The cDNA of Clone 1000838788\_228-28-4-0-F7-F (SEQ ID NO:39) encodes the Reductase Protein (RP):  
 MVSGRFYLSCLLLGSLGSMCILFTIYWMQYWRGGFAWNGSIYMFNWHPLMVAGMVVF  
 YGGASLVYRLPQSWVGPKLPWKLLHAALHLMFVLTVVGLVAVFTFHNHGRTANLYSL  
 HSWLGITTVFLFGCQWFLGFAVLLPWASMWLRSLLKPIHVFFGAAILSLSIASVISGINEK  
 LFFSLKNTTPYHSLPSEAVFANSTGMLVVAFGLLVLYILLASSWKRPEPGILTDRQLLQL  
 RPSRPFPTVTVSVTGRQPYKSW (SEQ ID NO:40). Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:40 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 1000838788\_228-28-4-0-F7-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:39 described throughout the present application also pertain to the nucleic acids included in Clone 1000838788\_228-28-4-0-F7-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:39, SEQ ID NO:40, and Clone 1000838788\_228-28-4-0-F7-F. Also preferred are polypeptide fragments having a biological activity described herein and the polynucleotides encoding the fragments.

RP is a novel member of the cytochrome b561 family of transmembrane electron transfer proteins. RP supplies reducing equivalents by catalyzing the transfer of electrons across a membrane from a donor to an electron acceptor. This process depends on the interaction of

histidine residues within the protein and transition metals (usually iron). Also required are cofactors to act as electron donors and acceptors. Examples of electron donors include but are not limited to ascorbic acid, NADH, NADPH, flavins, and reducing polypeptides. Electron acceptors include but are not limited to semidehydroascorbic acid, NAD<sup>+</sup>, NADP<sup>+</sup>, oxidized flavin species, and electron-accepting polypeptide complexes. Therefore, RP requires membrane association, a transition metal cofactor, and electron donor/acceptor cofactors for activity. These "required components of RP activity" will be referred to hereafter as such.

Preferred embodiments of the invention include: (1) a composition comprising an RP polypeptide sequence of SEQ ID NO:40; (2) a composition comprising an RP polypeptide fragment having biological activity; (3) a composition comprising a polynucleotide sequence of SEQ ID NO:39 encoding an RP polypeptide; (4) a composition comprising a polynucleotide sequence encoding an RP polypeptide fragment having biological activity.

A method of reducing oxidized species of iron comprising the step of: contacting an RP polypeptide or polynucleotide construct comprising polynucleotides encoding an RP polypeptide with iron and a cell. Preferably, ferric iron is reduced to ferrous iron. Preferably, the cell is involved in iron-uptake. Further preferably, the cell is derived from duodenal or small intestinal epithelium. Further preferably, the cell is a brush border enterocyte.

A method of reducing monooxygenases comprising the step of: contacting an RP polypeptide or polynucleotide construct comprising polynucleotides encoding an RP polypeptide with a monooxygenase enzyme and a cell. Preferably, the monooxygenase is peptidylglycine alpha-amidating monooxygenase (PAM). Also preferred is the monooxygenase dopamine beta-hydroxylase (DBH). Preferably, the cell is an endocrine cell. Further preferably, the cell is a neuroendocrine cell.

A method of screening for molecules that bind and/ or inhibit the ability of RP polypeptides to transfer electrons comprising the steps: (1) contacting an RP polypeptide with a test molecule; (2) detecting test molecule binding to said RP polypeptide; and (3) detecting test molecule inhibiting of RP polypeptide biological activity. Preferably, a test molecule is immobilized on a semi-solid matrix.

Also preferred is a test molecule immobilized on a solid matrix. Preferably, a test molecule binding to RP polypeptide is detected using fluorescently-labelled RP antibody. Preferably, RP biological activity is detected using a common redox assay. Further preferably, RP biological activity is detected using an MTT reduction assay. Also further preferred is RP biological activity detected using an NBT reduction assay.

A method of inhibiting RP polypeptide-dependent electron transfer comprising the step in contacting an RP polypeptide with an RP polypeptide inhibitor.

RP polypeptides are capable of transferring electrons to iron species, for example, reducing ferric (III) iron to ferrous (II) iron. Non-heme associated Fe (III) is highly insoluble in the body,

while reduced Fe (II) is more readily absorbed. Thus, a method for reducing Fe (III) to Fe (II) is a highly desirable treatment for disorders such as hemolytic diseases (e.g., sickle cell anemia), hemoglobinopathies, low iron absorption, rheumatoid arthritis, hypoxia, anemias associated with pregnancy, end-stage renal failure, cancer chemotherapy, and AIDS (particularly in subjects who are being treated with zidovudine (AZT)), and chronic anemia. Furthermore, increased iron uptake enables rapid weight gain desired in livestock. In a preferred embodiment of the invention, an iron-reducing effective amount of RP polypeptides or a polynucleotide construct comprising polynucleotides encoding said polypeptide are used in a method to reduce oxidized species of iron. This method comprises the step of contacting a RP polypeptide or polynucleotide construct with required components of RP activity, iron, and cells. Preferred cells are those involved in iron-uptake. Further preferred cells are those of the duodenum and small intestinal epithelium such as brush border enterocytes [for review, see Siddiqi, S., et al. (2001) Curr. Opin. Gastroenterol. 17:110-7, which disclosure is hereby incorporated by reference in its entirety].

RP is expressed in neuroendocrine tissues where it is localized to secretory vesicles. RP supplies reducing ability (i.e., electrons) to monooxygenase enzymes, which play a role in biosynthesis and processing of catecholamines (e.g., dopamine and norepinephrine) and peptide hormones (e.g., neuropeptides, gonadotropins, somatotropins, thyrotropins, corticotropins, and lactotropins such as vasopressin, oxytocin, and insulin). In a preferred embodiment of the invention, a reducing effective amount of RP polypeptides or polynucleotides encoding said polypeptides are used in a method to reduce monooxygenases, thereby increasing the activity of these enzymes. This method comprises the step of contacting a RP polypeptide or polynucleotide construct with required components of RP activity, monooxygenase enzymes, and cells. Preferred monooxygenase enzymes include but are not limited to peptidylglycine alpha-amidating monooxygenase (PAM) and dopamine beta-hydroxylase (DBH). Preferred cells are those that express endogenous monooxygenases, such as cells of the adrenal medulla, pituitary gland, and other neural and endocrine tissues.

Delivery of RP polypeptide or a polynucleotide construct comprising polynucleotides encoding RP polypeptide to cells is accomplished by methods common to the art such as transfection, electroporation, or microinjection. Additional methods of contacting said polynucleotide construct with cells include but are not limited to: lipid vesicle delivery (including micelles, viral envelope components, liposomes, and modified versions of these) as discussed in U.S. Patent 6,110,490, U.S. Patent 5,019,369, and P.C.T. 9704748, which disclosures are hereby incorporated by reference in their entireties; viral transduction (including attenuated lentiviral and adenoviral systems) as discussed in U.S. Patent 6,204,060, which disclosure is hereby incorporated by reference in its entirety; and delivery of naked polynucleotides (preferably to cells of the gastrointestinal tract) as discussed in U.S. Patent 6,225,290, which disclosure is hereby incorporated by reference in its entirety.

An example method of delivery comprises steps: i) compressing a polynucleotide construct, preferably comprising the polynucleotides encoding RP polypeptide operably linked to an expression control element (e.g., a CMV promoter to direct constitutive expression), into a lipid vesicle derived from any of the following list: viral envelopes, liposomes, micelles, gangliosides and modified versions of these, preferably GM-1 ganglioside and phosphatidylserine, as described in U.S. Patent 6,180,603, U.S. Patent 6,110,490 or P.C.T. 9704748, which disclosures are hereby incorporated by reference in their entireties; ii) targeting the lipid vesicle to specific cells, for example, by embedding a targeting moiety into the lipid envelope (e.g., growth hormone secretagogue for pituitary localization); iii) contacting the targeted vesicle with specific cells by methods common to the art such as injection or inhalant (U.S. Patent 6,110,490, P.C.T. 9704748, and U.S. Patent 6,180,603, which disclosures are hereby incorporated by reference in their entireties).

In an additional example of delivery, a polynucleotide construct comprising polynucleotides encoding the RP polypeptide operably linked to an expression control element (e.g., a CMV promoter to direct constitutive expression or a brush border-specific promoter such as the sucrase promoter) is delivered orally (e.g., in a physiologically-acceptable liquid, slurry, syrup, paste, powder, pill, or capsule form) to increase iron absorption by brush border enterocytes in the duodenum. Said naked polynucleotide construct may be modified to specifically target certain cells of the intestine, for example, by adding an oligosaccharide modification specific for brush border cell lectins (e.g., wheat germ agglutinin). Said naked polynucleotide construct may further provide for site-specific integration into the genome of the target intestinal cell. For example, said construct can be modified such that polynucleotides encoding RP polypeptide and an operably linked promoter to are flanked by the position-specific integration markers of *Saccharomyces cerevisiae* Ty3 (U.S. Patent 5,292,662, which disclosures are hereby incorporated by reference in their entirety).

Further included in the present invention are methods of inhibiting the above RP activities using an inhibitor of RP. Thus, a preferred embodiment of the present invention is a method of inhibiting RP polypeptide-dependent electron transfer (including reduction of ferric iron to ferrous iron and reduction of monooxygenase enzymes) by contacting RP polypeptides with RP polypeptide inhibitors. A further embodiment of the invention is a method of screening for compounds that bind and/ or inhibit the ability of RP polypeptides to transfer electrons. This method comprises the steps of: i) contacting an RP polypeptide with a test compound; and ii) detecting whether said test compound binds and/ or inhibits RP polypeptide reducing activity. Detection of RP polypeptide binding is accomplished by methods common to the art (e.g., by immobilizing said test compound on a solid or semi-solid matrix and detecting RP polypeptides by fluorescently-labelled RP antibody). Inhibition of RP polypeptide reducing activity is measured using common assays to detect redox and electron transfer activity, such as MTT reduction (Chakrabarti, R., et al. (2000) J.

Cell Biochem. 18:133-8, which disclosure is hereby incorporated by reference in its entirety) or NBT reduction [Meerhof, L. and Roos, D. (1986) J. Leukoc. Biol. 39:699-711, which disclosure is hereby incorporated by reference in its entirety].

**Protein of SEQ ID NO:42 (Internal designation Clone 1000943975\_160-213-2-0-A5-F)**

- 5       The cDNA of Clone 1000943975\_160-213-2-0-A5-F (SEQ ID NO:41) encodes the Small Secreted Serine Protease Inhibitor (SSSPI) comprising the amino acid sequence:  
MPACRLGPLAAALLLSLLLFGLVSGTGAETGVCPQLQADQNCTQECVSDSECADNLK  
CCSAGCATFCSLPNDKEGSCPQVNINFPQLGLCRDQCQVDSQCPGQMKCCRNGCGKVSC  
VTPNF (SEQ ID NO:42). Accordingly, it will be appreciated that all characteristics and uses of  
10 the polypeptides of SEQ ID NO:42 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 1000943975\_160-213-2-0-A5-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:41 described throughout the present application also pertain to the nucleic acids included in Clone 1000943975\_160-213-2-0-A5-F. A preferred embodiment of the invention is directed  
15 toward the compositions of SEQ ID NO:41, SEQ ID NO:42, and Clone 1000943975\_160-213-2-0-A5-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding said fragments.

- The Small Secreted Serine Protease Inhibitor (SSSPI) includes two WAP (whey acidic protein)/ four-disulfide core domains, which are commonly found in serine protease inhibitors.  
20 SSSPI is extremely stable due to the presence of extensive intramolecular disulfide bonds. The biological activity of SSSPI is to inhibit protein degradation by serine proteases determined, for instance, by tracking protein degradation by methods common to the art (e.g., Coomassie Blue stain). Furthermore, SSSPI activity is associated with retarding growth in tissues that include smooth muscle, colon, ovarian, and mammary tissues.

- 25       In a preferred embodiment of the invention, SSSPI polypeptides or fragments thereof are used to screen libraries of compounds for formation of binding complexes between SSSPI polypeptide and the agent being tested. The fragment employed in such screening may be free in solution, affixed to a solid support, borne on a cell surface, or located intracellularly. The formation of binding complexes is measured by methods known in the art (e.g., fluorescent  
30 labeling or green fluorescent protein tagging of the test agent, SSSPI polypeptides, or antibodies against either). A preferred method for screening provides for high throughput screening of compounds having suitable binding affinity to SSSPI polypeptide. An example of this method comprises the steps: i) synthesizing large numbers of different small test compounds onto a solid substrate, such as plastic pins; ii) reacting test compounds with SSSPI polypeptides and washed;  
35 iii) detecting bound SSSPI polypeptides by methods known in the art. Alternatively, SSSPI polypeptides are coated directly onto plates or immobilized using non-neutralizing antibodies and used in the aforementioned screening techniques. This method is applied, for example, to

detecting protease levels in a test solution or to screening for molecules that interact with SSSPI as discussed in the following embodiment. In another embodiment of the invention, binding complexes of SSSPI polypeptide and the aforementioned test agents are used in a method to screen for compounds that inhibit interaction of SSSPI polypeptide with serine protease substrates. This method comprises the steps: i) allowing SSSPI polypeptide-test agent binding complex to form; ii) adding SSSPI substrate (such as elastase); iii) measuring SSSPI binding to substrate directly or indirectly by methods common in the art (e.g., fluorescent labeling of the substrate molecule or of an antibody against said substrate). This method is applied, for example, to screening for molecules that inhibit SSSPI biological activity.

- 10 In a preferred embodiment of the invention, a method of inhibiting protein degradation with a biologically active SSSPI polypeptide or a polynucleotide construct comprising polynucleotides encoding said polypeptide is provided. This method comprises the step of contacting a protein degradation-inhibiting effective amount of SSSPI polypeptide with proteins in a solution of appropriate pH and salt concentration to allow SSSPI biological activity (e.g., buffered saline). In an additional embodiment, SSSPI polypeptide is combined with other protease inhibitors and used in a method to inhibit protein degradation. This method comprises the steps: combining a protein degradation-inhibiting effective amount of SSSPI polypeptide with effective amounts of other protease inhibitors to form a protease inhibitor cocktail and contacting said cocktail with proteins in a solution of appropriate pH and salt concentration to allow SSSPI biological activity. Preferred protease inhibitors are of a different specificity than SSSPI to maximize the protease-inhibiting effectiveness of the cocktail, such as Kunitz-, trypsin inhibitor-like cysteine-rich domain (TIL)-, thyroglobulin-, Kazal-, and netrin (NTR)- type protease inhibitors.

- Biologically acceptable salts of the SSSPI polypeptide also fall within the scope of the invention. The term "biologically acceptable salts" as used herein means an inorganic acid addition salt such as hydrochloride, sulfate, and phosphate, or an organic acid addition salt such as acetate, maleate, fumarate, tartrate, and citrate. Examples of biologically acceptable metal salts are alkali metal salts such as sodium salt and potassium salt, alkaline earth metal salts such as magnesium salt and calcium salt, aluminum salt, and zinc salt. Examples of biologically acceptable organic amine addition salts are salts with morpholine and piperidine. Examples of biologically acceptable amino acid addition salts are salts with lysine, glycine, and phenylalanine.

- Compounds provided herein can be formulated into "physiologically acceptable compositions" by admixture with physiologically acceptable nontoxic excipients and carriers. Such compositions may be prepared for use in parenteral administration, particularly in the form of liquid solutions or suspensions; oral administration, particularly in the form of tablets or capsules; intranasally, particularly in the form of powders, nasal drops, or aerosols; dermally, via, for example, transdermal patches; or prepared in other suitable fashions for these and other forms of administration as will be apparent to those skilled in the art.

Common excipients include, for example, sterile water or saline, polyalkylene glycols such as polyethylene glycol, oils of vegetable origin, and hydrogenated naphthalenes. Further excipient formulations include but are not limited to lactose, polyoxyethylene-9-lauryl ether, glycocholate, deoxycholate, salicylate, citric acid, oily or gel-like solutions and lipophilic emulsions. Potentially  
5 useful parenteral delivery systems for these active compounds include ethylene-vinyl acetate copolymer particles, osmotic pumps, implantable infusion systems, and liposomes. The invention can be employed as the sole active agent or can be used in combination with other active ingredients which could facilitate inhibition of serine proteases.

Protease activity is associated with tumor formation by mechanisms that include  
10 proteolytic processing of growth factors (e.g., insulin-like growth factor, fibroblast growth factor (FGF), epidermal growth factor (EGF), heparin-binding epidermal growth factor-like growth factor, tumor necrosis factor (TNF)-alpha, and transforming growth factor (TGF)-beta). Indeed, SSSPI is capable of inhibiting proliferation of prostate carcinoma cells and pulmonary artery smooth muscle by preventing proteolytic processing of insulin-like growth factor II and FGF,  
15 respectively. In a preferred embodiment of the invention, a protein degradation-inhibiting effective amount of SSSPI polypeptide is contacted with cells to inhibit proteolytic processing and degradation of proteins. Preferred cells are those expressing growth factors that require proteolytic processing to promote proliferation, such as those listed above. Examples of preferred cells include those from the lung, gastrointestinal tract, liver, skin, mammary gland, pancreas, ovary,  
20 prostate gland, and vascular smooth muscle and epithelia. This method comprises the step of contacting a physiologically acceptable composition of SSSPI polypeptide with cells. Delivery of said composition to cells is accomplished as discussed above, as determined appropriate by one skilled in the art.

An additional embodiment of the invention provides a method of introducing a  
25 polynucleotide construct comprising polynucleotides encoding SSSPI polypeptides to cells to inhibit proteolytic processing and degradation of proteins. Preferred cells are those expressing growth factors that require proteolytic processing to promote proliferation (e.g., insulin-like growth factor, FGF, EGF, heparin-binding epidermal growth factor-like growth factor, TNF-alpha, and TGF-beta) or cells that contact said cells. Examples of preferred cells include those from the lung,  
30 gastrointestinal tract, liver, skin, mammary gland, pancreas, ovary, prostate gland, and vascular smooth muscle and epithelia. Preferred polynucleotide constructs comprise polynucleotides encoding SSSPI polypeptide operably linked to an expression control element such as a promoter. Preferred expression control elements direct expression of SSSPI polypeptide in amount effective to inhibit protein degradation. Examples include the CMV promoter for constitutive expression or  
35 a tissue-specific promoter, such as the human glandular kallikrein-2 promoter for expression in androgen receptor-positive prostate cancer cells. A physiologically acceptable composition comprising the polynucleotide construct is introduced to cells using methods common to the art

such as electroporation or transfection. Additional delivery methods of said physiologically acceptable composition include but are not limited to: lipid vesicle delivery (including micelles, viral envelope components, liposomes, and modified versions of these) as discussed in U.S. Patent 6110490, U.S. Patent 5019369, and P.C.T. 9704748, which disclosures are hereby incorporated by reference in their entirety; viral transduction (including attenuated lentiviral and adenoviral systems) as discussed in U.S. Patent 6204060, which disclosure is hereby incorporated by reference in its entirety; and delivery of a physiologically acceptable composition comprising naked polynucleotides (for example, to cells of the gastrointestinal tract) as discussed in U.S. Patent 6225290, which disclosure is hereby incorporated by reference in its entirety.

10 SSSPI is capable of inhibiting serine proteases implicated in degenerative disorders including but not limited to thrombin, human leukocyte elastase, pancreatic elastase, trypsin, chymase, and cathepsin G. Thrombin is produced in the blood coagulation cascade and is implicated disorders such as thrombophlebitis, thrombosis, other bleeding disorders, and asthma. Human leukocyte elastase is implicated in tissue degenerative disorders such as rheumatoid

15 arthritis, osteoarthritis, atherosclerosis, bronchitis, cystic fibrosis, and emphysema. Pancreatic elastase and trypsin are implicated soft tissue degradation, particularly in cases of pancreatitis. Chymase, an enzyme important in angiotensin synthesis, is implicated in disorders such as hypertension, myocardial infarction, and coronary heart disease. Cathepsin G is implicated in abnormal connective tissue degradation, particularly in the lung. In the extreme, serine proteases

20 including but not limited to those mentioned above, kallikrein, and prostate specific antigen (PSA) are involved in tumor formation through proteolytic remodeling of extracellular matrix (ECM) proteins. This proteolytic remodeling may result in disruption of the integrity of tissue epithelial lining and basement membranes and result in metastasis. In a preferred embodiment of the invention, a protein degradation-inhibiting effective amount of SSSPI polypeptides are applied to

25 cells to inhibit protein degradation and resulting tissue or ECM degeneration. This method comprises the step of contacting a physiologically acceptable composition comprising SSSPI polypeptides with cells. Preferred cells include those diagnosed or at risk of degenerative disorders as a result of serine protease activity, such as those lung, gastrointestinal tract, liver, skin, mammary gland, pancreas, ovary, prostate gland, bone and cartilage, and vascular smooth muscle

30 and epithelia. Further preferred cells include those diagnosed or at risk of tumor invasion as a result of serine protease activity such as those involved in formation of epithelial linings, basement membranes, and ECM (e.g., epithelial cells and fibroblasts). Delivery of said composition to cells is accomplished as discussed above, as determined appropriate by one skilled in the art.

In a further embodiment of the invention, SSSPI polypeptides or fragments thereof are

35 used in a method to detect serine proteases. This method is directed toward diagnosis of the aforementioned disorders and diseases. An example of this method comprises the steps of contacting SSSPI polypeptides with a biological fluids (e.g., cell culture media, blood, serum, cell

suspensions or samples) suspected of containing serine proteases, washing, and detecting serine protease-SSSPI complexes. Detection of said complexes is accomplished by methods common to the art such as competition with a fluorescently-labeled neutralizing antibody.

**Protein of SEQ ID NO:44 (Internal designation Clone 147441\_106-025-2-0-C11-F)**

- 5 The cDNA of Clone 147441\_106-025-2-0-C11-F (SEQ ID NO:43) encodes the Carboxypeptidase Inhibitor-1 (CPI-1):
- MQGTPGGGTRPGSPVDRRTLLVFSFILAAALGQMNFTGDQVLRVLAKDEKQLSLGDL  
GLKPQKVDFWRGPARPSLPVDMRVPFSELKD (SEQ ID NO:44). Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:44 described
- 10 throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 147441\_106-025-2-0-C11-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:43 described throughout the present application also pertain to the nucleic acids included in Clone 147441\_106-025-2-0-C11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:43,
- 15 SEQ ID NO:44, and Clone 147441\_106-025-2-0-C11-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

CPI-1 is a 91 amino acid protein that is highly homologous to the amino-terminal "prepro" region of preprocarboxypeptidase. The "pre" region represents a signal peptide while the "pro" region inhibits carboxypeptidase enzyme activity by binding to the active site of the enzyme before

20 being proteolytically removed. Proteolytic cleavage of procarboxypeptidase results in formation of mature, active carboxypeptidase. Proteolytic processing of procarboxypeptidase (e.g., by trypsin) relies on the carboxy-terminus of the "pro" region, which is absent in CPI-1. CPI-1 therefore acts as a small, independent inhibitor of carboxypeptidase activity that is not recognized by carboxypeptidase-specific proteases. Carboxypeptidases comprise a family of proteins that

25 function in many physiological processes. These proteins remove a wide range of carboxyl-terminal amino acids, and in doing so are able to activate, inactivate, and modulate enzyme and peptide hormone activity, as well as participate in peptide degradation and amino acid absorption. Active forms of mammalian carboxypeptidases may be secreted or located in lysosomes where they regulate intracellular protein processing, degradation and turnover. The "biological activity"

30 of CPI-1 polypeptide is defined as the ability to inhibit carboxypeptidase activity. Carboxypeptidase activity may be measured by methods common to the art, such as incubation of a test sample with a radiolabeled Bolton-Hunter reagent-coupled peptide substrate (Normant, E., et al. (1995) Proc. Natl. Acad. Sci. 92:12225-9). "Carboxypeptidase" is used herein to refer to any member of the carboxypeptidase family.

- 35 Preferred embodiments of the present invention include: (1) a composition, comprising a CPI-1 polypeptide sequence of SEQ ID NO:44; (2) a composition, comprising a CPI-1 polypeptide fragment having a carboxypeptidase-inhibiting biological activity; (3) a composition, comprising a

polynucleotide sequence of SEQ ID NO:43 encoding a CPI-1 polypeptide; (4) a composition, comprising a polynucleotide sequence encoding a carboxypeptidase-inhibiting biologically active CPI-1 polypeptide fragment.

- 5 A method of inhibiting carboxypeptidase-mediated anti-fibrinolytic activity, comprising the step of: contacting an effective amount of a CPI-1 polypeptide or biologically active fragment thereof with carboxypeptidase in the bloodstream of an individual. Further preferably, CPI-1 polypeptide is delivered to a human.

- 10 A method of preventing or inhibiting the progression of carboxypeptidase-mediated pancreatitis, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a pancreatic cell.

A method of preventing or inhibiting the progression of carboxypeptidase-mediated pancreatic cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a pancreatic cell.

- 15 A method of preventing or inhibiting the progression of carboxypeptidase-mediated lung cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a lung cell.

A method of preventing or inhibiting the progression of carboxypeptidase-mediated ovarian cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with an ovarian cell.

- 20 A method of preventing or inhibiting the progression of carboxypeptidase-mediated larynx cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a larynx cell.

- 25 A method of preventing or inhibiting the progression of carboxypeptidase-mediated uterine cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a uterine cell.

A method of preventing or inhibiting the progression of carboxypeptidase-mediated hepatic cancer, comprising the step of: contacting a CPI-1 polypeptide or biologically active fragment thereof with a hepatic cell.

- 30 A method of binding an antibody or antibody fragment to a CPI-1 polypeptide comprising the step of: contacting said antibody or antibody fragment with a biological sample.

A method of using an antibody or antibody fragment that specifically binds CPI-1 polypeptides or fragments thereof in a detection assay comprising the steps of: contacting said antibody or antibody fragment with a biological sample; and detecting antibody or antibody fragment binding to said sample.

- 35 A further preferred method comprises the additional step of: contacting a second antibody, or antibody fragment, that does not bind CPI-1 polypeptides or fragments thereof with said biological sample.

Further preferably, the first and/ or second antibodies or antibody fragments are modified with detectable molecular tags.

Further preferably, the biological sample is a blood sample or a tissue sample.

Further preferably, the detection assay is used for purposes of diagnosis.

- 5        A method of using an antibody or antibody fragment that binds CPI-1 polypeptides or fragments thereof to inhibit CPI-1 biological activity and facilitate carboxypeptidase activity, comprising the step of: contacting said antibody or antibody fragment with CPI-1 polypeptides or biologically active fragments thereof.

- 10        The coagulation and fibrinolytic pathways are balanced to produce blood clotting and clot degradation, respectively, at appropriate times. Carboxypeptidase activity is anti-fibrinolytic, i.e., carboxypeptidase abrogates clot degradation, most likely by inhibiting plasminogen activation. In a preferred embodiment of the invention, a carboxypeptidase-inhibiting effective amount of a CPI-1 polypeptide, fragment thereof, or a polynucleotide encoding said polypeptide is used to inhibit carboxypeptidase-mediated blood clot formation and retention. This method may be directed
- 15        toward facilitating anti-coagulant activity as desired in cases such as immobilization, thrombophilia, hereditary thrombophilia, stroke, myocardial infarction, coronary artery disease, malignant conditions, during and after surgical procedures, and in cases of increased risk of blood clots associated with medications. Preferably, this method is directed toward treatment of these conditions in a human. This method comprises the step of contacting a CPI-1 polypeptide or a
- 20        biologically active fragment thereof with carboxypeptidase by administering a CPI-1 polypeptide to and individual. A preferred method of delivering CPI-1 polypeptides or biologically active fragments thereof to an individual includes direct, intravenous injection of said polypeptides or fragments in a physiologically acceptable solution (e.g., pH-buffered isotonic saline solutions, pH-buffered isotonic saline solutions modified by addition of viscous elements such as glycerol).
- 25        An additional preferred method of delivering CPI-1 polypeptides or fragments to an individual comprises the step of introducing a polynucleotide construct comprising polynucleotides encoding CPI-1 polypeptides or biologically active fragments thereof into a cell. Preferred cells are those lining the bloodstream, such as vascular endothelial cells, vascular smooth muscle cells, and fibroblasts. Additional preferred cells are those that travel through the bloodstream, such as
- 30        hematopoietic cells and their precursors, lymphocytes, macrophages, eosinophils, neutrophils, and red blood cells. Preferred polynucleotide constructs comprise an expression control element operably linked to polynucleotides encoding a CPI-1 polypeptide or biologically active fragment thereof. Examples of commercially available expression control units include but are not limited to a CMV promoter for constitutive expression or a tetracycline-repressible promoter for regulated
- 35        expression. Said polynucleotide construct is delivered to the cell by methods determined appropriate for the cell type. Delivery to cells that travel through the bloodstream may be accomplished by methods common to the art such as transfection or electroporation. Cells

carrying the polynucleotide construct are then introduced to the bloodstream by, for instance, injection. Delivery to cells that line the bloodstream may be accomplished by methods including but not limited to lipid vesicles or viral transduction, as described in any one of the list: U.S. Patent 5616565, U.S. Patent 6110490, U.S. Patent 6204060, and P.C.T. 9704748 which disclosures are hereby incorporated by reference in their entireties. Lipid vesicles may be derived from elements including but not limited to: viral envelopes, liposomes, micelles, and modified versions of these, as described in U.S. Patent 6110490 or P.C.T. 9704748, which disclosures are hereby incorporated by reference in their entireties. Lipid vesicles or viruses may further be targeted to specific cells, for example, by embedding a member of a receptor-receptor ligand pair into the lipid envelope (e.g., VEGF/VEGFR for targeting to vascular endothelial cells).

While carboxypeptidase activity is required for normal protein processing in the pancreas, higher than normal levels of activity lead to pancreatitis, or destruction and inflammation of the pancreas. Pancreatitis often leads to pancreatic cancer. Carboxypeptidase is active in the extracellular space of the pancreas as well as in vacuolar compartments such as lysosomes. In a preferred embodiment of the invention, a carboxypeptidase-inhibiting effective amount of CPI-1 polypeptides, biologically active fragments thereof, or polynucleotides encoding said polypeptides are used to prevent or inhibit progression of pancreatitis or pancreatic cancer. This method comprises the step of contacting a physiologically acceptable solution comprising a CPI-1 polypeptide or biologically active fragment thereof with a pancreatic cell. Said polypeptides may be delivered, for example, by implanting a CPI-1 polypeptide-releasing stent surgically or via catheter (U.S. Patent 5,500,013 and U.S. Patent 5,449,382, which disclosures are hereby incorporated by reference in their entireties). Polypeptides may further be delivered by direct injection (catheter or syringe) into the pancreatic organ. A further preferred method of delivering CPI-1 polypeptides or biologically active fragments thereof includes introducing a polynucleotide construct comprising polynucleotides encoding said polypeptides into a pancreatic cell. This method has the advantage of contacting CPI-1 polypeptides with intracellular compartments of carboxypeptidase activity. Said polynucleotide construct may further include an expression control element operably linked to polynucleotides encoding CPI-1 polypeptides or biologically active fragments thereof. Said polynucleotide construct may be delivered to a pancreatic cell by methods including but not limited to lipid vesicles or viral transduction, as described in any one of the list: U.S. Patent 5,616,565, U.S. Patent 6,110,490, U.S. Patent 6,204,060, and P.C.T. 9704748 which disclosures are hereby incorporated by reference in their entireties. Lipid vesicles may be derived from elements including but not limited to the following list: viral envelopes, liposomes, micelles, and modified versions of these, as described in U.S. Patent 6,110,490 or P.C.T. 9704748, which disclosures are hereby incorporated by reference in their entireties. Lipid vesicles or viruses may further be targeted to specific cells, for example, by embedding a member of a receptor-receptor ligand pair into the lipid envelope.

Aside from pancreatic cancer, higher than normal levels of carboxypeptidase activity are found in cancers that include: lung, ovary, larynx, uterus, liver, stomach, and breast cancers. Carboxypeptidase activity leads to an increase in inflammatory cytokines, such as Tumor Necrosis Factor (TNF)-alpha. Therefore, carboxypeptidase-mediated tumorigenesis results from

- 5 inflammation and destruction in a number of tissue types. As a preferred embodiment of the invention, a carboxypeptidase-inhibiting effective amount of CPI-1 polypeptides, biologically active fragments thereof, or polynucleotides encoding said polypeptides are used to prevent or inhibit progression of cancers. Preferred cancers include those listed above. This method comprises the step of contacting a physiologically acceptable solution comprising a CPI-1
- 10 polypeptide or biologically active fragment thereof with a cell. Preferred cells include those of the lung, ovary, larynx, uterus, liver, stomach, and breast. Further preferred cells are those at risk of or displaying cancerous or precancerous pathology as is commonly determined by those skilled in the art (e.g., loss of contact inhibition, abnormal cell size or shape). CPI-1 polypeptides, biologically active fragments thereof, or polynucleotides encoding said polypeptides are delivered to a specific
- 15 cell by methods common to the art such as those discussed herein.

- In an additional embodiment of the invention, CPI-1 polypeptides or fragments thereof are used to generate antibodies (or antibody fragments) that specifically bind to CPI-1 polypeptides or fragments thereof (detAbs for "detection antibodies") and/ or inhibit the biological activity of CPI-1 polypeptides or fragments thereof (inhAbs for "inhibitory antibodies"). Antibodies may be
- 20 polyclonal or monoclonal and may be generated by any method known to one skilled in the art.

- In a preferred embodiment of the invention, antibodies or antibody fragments that specifically bind and inhibit CPI-1 biological activity (inhAbs) are used to facilitate carboxypeptidase activity. This method may be directed toward increasing carboxypeptidase-mediated anti-fibrinolytic activity for example, to prevent or treat bleeding disorders. This method
- 25 may alternatively be directed toward increasing carboxypeptidase-mediated uptake of low density lipoprotein (LDL) particles by macrophages for example, to prevent or treat high blood pressure or atherosclerosis. This method comprises the step of contacting inhAbs with CPI-1. A preferred method of contact includes injection of a physiologically acceptable solution comprising inhAbs to the bloodstream of an individual at risk of or suffering from a bleeding disorder or high LDL
- 30 levels.

- In a further preferred embodiment of the invention, antibodies or antibody fragments that bind CPI-1 polypeptides or fragments thereof (detAbs) are used in assays to bind and/ or detect CPI-1 polypeptides or fragments thereof. This method may be directed toward *in vitro* uses such as purification of CPI-1 or carboxypeptidase polypeptides for drug development. An example of
- 35 this method comprises the steps of: immobilizing a detAb on a solid or semi-solid matrix (e.g., sepharose); and exposing said immobilized detAb with a biological solution comprising proteins, preferably CPI-1 polypeptides or fragments thereof. This method may further be directed toward

- diagnosis of pancreatitis, pancreatic cancer, LDL-mediated disorders, and clotting disorders such as hemophilia, thrombophilia, hereditary thrombophilia, stroke, myocardial infarction, coronary artery disease, malignant conditions, and blood clots. This method comprises the steps of: contacting a detAb, preferably a detectably-labeled detAb (e.g., conjugated to a fluorescent tag),
- 5 with a biological sample, preferably a tissue or blood sample; and detecting detAb binding to said sample. A further step of contacting a second antibody or antibody fragment that does not bind CPI-1 polypeptides or fragments thereof may be added to determine the specific nature of the protein detected by the first antibody or antibody fragment. The second antibody or antibody fragment is preferably labeled with a detectable molecular tag such as a fluorescent molecule.
- 10 Further preferably, a different molecular tag than that used by the first antibody or antibody fragment is used with the second antibody or antibody fragment.

**Protein of SEQ ID No:46 (Internal designation Clone 124610\_113-003-3-0-H5-F)**

- The polypeptides of SEQ ID NO:46 are encoded by the polynucleotides of SEQ ID NO:45 of Clone 124610\_113-003-3-0-H5-F. It will be appreciated that all characteristics and uses of the
- 15 polynucleotides of SEQ ID NO:45 and polypeptides of SEQ ID NO:46, described throughout the present application also pertain to the human cDNA of Clone 124610\_113-003-3-0-H5-F and the polypeptides encoded thereby. The gene of SEQ ID NO:45 is located on chromosome 17, encodes a human retinoic acid-inducible regulator of growth arrest and differentiation and is hereby referred to as RET-A-MODULIN comprising the polypeptide

PYSDPHIPPVSKNAKARTRKCSLVSGHGRENKSCRGWGWGQGF. A preferred embodiment
- 25 of the invention is directed toward the compositions of SEQ ID NO:45, SEQ ID NO:46, and Clone 124610\_113-003-3-0-H5-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

- A preferred embodiment of the invention is directed towards using compositions comprising RET-A-MODULIN and other preferred compositions in a method for inhibiting
- 30 neoplastic cell growth, killing neoplastic cells and treating cancer. More particularly, the invention concerns methods and compositions to inhibit cellular proliferation of neoplastic cells, induce cytotoxicity in neoplastic cells and kill neoplastic cells (e.g., carcinomas, melanoma, and lymphoid tumors such as acute myelocytic leukemia (AML)), wherein said methods comprises contacting cells with a proliferation-inhibiting amount of RET-A-MODULIN or other sequences of the
- 35 invention. The method of suppressing neoplastic cell growth comprises the effects selected from the group consisting of: (a) inhibiting cell growth or proliferation; (b) killing said neoplastic cells; (c) inducing apoptosis in said neoplastic cells; (d) inducing necrosis in said neoplastic cells;

(e) preventing or inhibiting neoplastic cell invasion; and (f) preventing or inhibiting neoplastic cell metastasis. In a preferred embodiment, the neoplastic are cancerous or from a tumor. In another aspect of the invention, said neoplastic cells are selected from the group consisting of bladder carcinoma, hepatocellular carcinoma, hepatoblastoma, rhabdomyosarcoma, ovarian carcinoma, cervical carcinoma, lung carcinoma, breast carcinoma, squamous cell carcinoma in head and neck, esophageal carcinoma, thyroid carcinoma, astrocytoma, ganglioblastoma, neuroblastoma, lymphoma, myeloma, sarcoma and neuroepithelioma. In yet another aspect of the invention, said neoplastic cells are malignant or benign. Further included in the invention are the following protein sequences:

- A preferred embodiments of the invention comprise physiologically acceptable compositions and methods of treating cancer in a patient (such as prostate cancer, skin  
 15 cancer/melanoma, pancreatic carcinoma, colon cancer, melanoma, ovarian cancer, liver cancer, small cell lung carcinoma, non-small cell lung carcinoma, cervical cancer, breast cancer, bladder cancer, brain cancer, neuroblastoma/glioblastoma, leukemia, lymphoma, head and neck cancer, kidney cancer, myeloma and ovarian cancer) characterized by proliferation of neoplastic cells which comprises administering to the patient an amount of a polypeptide of the invention, effective  
 20 to: (a) selectively induce apoptosis and/or necrosis in such neoplastic cells and thereby inhibit their proliferation; (b) inhibit cell growth and proliferation of the neoplastic cells; (c) inhibit invasion of the neoplastic cells; (d) inhibit metastasis of the neoplastic cells; (e) kill neoplastic cells; (f) preferentially inhibit cell growth and proliferation of the neoplastic cells; and (g) preferentially kill neoplastic cells. RET-A-MODULIN or other proteins of the invention or  
 25 fragments thereof can be used in combination with one or more of various anticancer agents known as cancer chemotherapeutic agents and/or radiation therapy. The active ingredient compound of the invention which can produce an excellent anticancer effect can thus markedly promote the effect of the other anticancer agent or agents used in combination, to produce a synergistic effect. Therefore, even when the partner anticancer agent or agents are used in doses much smaller than  
 30 the usual doses, a satisfactory anticancer effect can be obtained, whereby the adverse effects of the partner anticancer agent or agents can be minimized. As such chemotherapeutic agents included but not limited to, for example, 5-fluorouracil (5-FU; Kyowa Hakko Kogyo), mitomycin C (Kyowa Hakko Kogyo), futraful (FT-207; Taiho Pharmaceutical), endoxan (Shionogi & Co.) and toyomycin (Takeda Chemical Industries). In addition, the apoptosis regulating composition of the  
 35 present invention may be administered with a vitamin D derivative to further enhance its cytotoxic characteristics (United States Patent 6,087,350). The anti-cancer agents of the present invention may be combined with an anti-oestrogen compound such as tamoxifen or anti-progesterone such as

onapristone (see, EP 616812) in dosages known for such molecules.

The pharmaceutically and physiologically acceptable compositions utilized in this invention may be administered by any number of routes including, but not limited to, parenteral, subcutaneous, intracranial, intraorbital, intracapsular, intraspinal, intracisternal, intrapulmonary (inhaled), oral, intravenous, intramuscular, intra-arterial, intramedullary, intrathecal, intraventricular, transdermal, subcutaneous, intraperitoneal, intranasal, enteral, topical, sublingual, or rectal means. In addition to the active ingredients, these pharmaceutically and physiologically acceptable compositions may contain suitable physiologically acceptable carriers comprising excipients and auxiliaries, which facilitate processing of the active compounds into preparations, which can be used pharmaceutically. Further details on techniques for formulation and administration may be found in the latest edition of Remington's Pharmaceutical Sciences (Maack Publishing Co. Easton, Pa). Pharmaceutically and physiologically acceptable compositions for oral administration can be formulated using physiologically acceptable carriers well known in the art in dosages suitable for oral administration. Such carriers enable the pharmaceutically and physiologically acceptable compositions to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions, and the like, for ingestion by the patient. Pharmaceutical preparations for oral use can be obtained through a combination of active compounds with solid excipient, suitable mixture is optionally grinding, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients are carbohydrate or protein fillers, such as sugars, including lactose, sucrose, mannitol, or sorbitol; starch from corn, wheat, rice, potato, or other plants; cellulose, such as methyl cellulose, hydroxypropylmethyl-cellulose, or sodium carboxymethylcellulose; gums including arabic and tragacanth; and proteins such as gelatin and collagen. If desired, disintegrating or solubilizing agents may be added, such as the cross-linked polyvinyl pyrrolidone, agar, alginic acid, or a salt thereof, such as sodium alginate.

Dragee cores may be used in conjunction with suitable coatings, such as concentrated sugar solutions, which may also contain gum arabic, talc, polyvinylpyrrolidone, carbopol gel, polyethylene glycol, and/or titaniumdioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for product identification or to characterize the quantity of active compound, i.e., dosage.

Pharmaceutical preparations, which can be used orally, include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a coating, such as glycerol or sorbitol. Push-fit capsules can contain active ingredients mixed with filler or binders, such as lactose or starches, lubricants, such as talc or magnesium stearate, and, optionally, stabilizers. In soft capsules, the active compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid, or liquid polyethylene glycol with or without stabilizers. Pharmaceutical formulations suitable for parenteral administration may be formulated in aqueous solutions, preferably in

physiologically compatible buffers such as Hanks solution, Ringer's solution, or physiologically buffered saline. Aqueous injection suspensions may contain substances, which increase the viscosity of the suspension, such as sodium carboxymethylcellulose, sorbitol, or dextran.

Additionally, suspensions of the active compounds may be prepared as appropriate oily injection  
5 suspensions. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes. Optionally, the suspension may also contain suitable stabilizers or agents, which increase the solubility of the compounds to allow for the preparation of highly, concentrated solutions. For topical or nasal administration, penetrants appropriate to the particular barrier to be permeated are used in the  
10 formulation. Such penetrants are generally known in the art. The pharmaceutically and physiologically acceptable compositions of the present invention may be manufactured in a manner that is known in the art, e.g., by means of conventional mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping, or lyophilizing processes.

The pharmaceutical composition may be provided as a salt and can be formed with many  
15 acids, including but not limited to, hydrochloric, sulfuric, acetic, lactic, tartaric, malic, succinic, etc. Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free base forms. In other cases, the preferred preparation may be a lyophilized powder which may contain any or all of the following: 1-50 mM histidine, 0.1%-2% sucrose, and 2-7% mannitol, at a pH range of 4.5 to 5.5, that is combined with buffer prior to use. After pharmaceutically and  
20 physiologically acceptable compositions have been prepared, they can be placed in an appropriate container and labeled for treatment of an indicated condition. For administration of RET-A-MODULIN, such labeling would include amount, frequency, and method of administration. Pharmaceutically and physiologically acceptable compositions suitable for use in the invention include compositions wherein the active ingredients are contained in an effective amount to  
25 achieve the intended purpose. The determination of an effective dose is well within the capability of those skilled in the art. For any compound, the therapeutically effective dose can be estimated initially either in cell culture assays, e.g., of neoplastic cells, or in animal models, usually mice, rabbits, dogs, or pigs. The animal model may also be used to determine the appropriate concentration range and route of administration. Such information can then be used to determine  
30 useful doses and routes for administration in humans. Those of ordinary skill in the art are well able to extrapolate from one model (be it an *in vitro* or an *in vivo* model). A therapeutically effective dose refers to that amount of active ingredient, for example RET-A-MODULIN polypeptides or other proteins of the invention or fragments thereof, which ameliorates the symptoms or condition. Therapeutic efficacy and toxicity may be determined by standard  
35 pharmaceutical procedures in cell cultures or experimental animals, e.g., ED50 (the dose therapeutically effective in 50% of the population) and LD50 (the dose lethal to 50% of the population). The dose ratio between therapeutic and toxic effects is the therapeutic index, and it

can be expressed as the ratio, LD50/ED50. Pharmaceutically and physiologically acceptable compositions, which exhibit large therapeutic indices, are preferred. The data obtained from cell culture assays and animal studies is used in formulating a range of dosage for human use. The dosage contained in such compositions is preferably within a range of circulating concentrations that include the ED50 with little or no toxicity. The dosage varies within this range depending upon the dosage form employed, sensitivity of the patient, and the route of administration. The practitioner, in light of factors related to the subject that requires treatment, will determine the exact dosage. Dosage and administration are adjusted to provide sufficient levels of the active moiety or to maintain the desired effect. Factors, which may be taken into account, include the severity of the disease state, general health of the subject, age, weight, and gender of the subject, diet, time and frequency of administration, drug combination(s), reaction sensitivities, and tolerance/response to therapy. Long-acting pharmaceutically and physiologically acceptable compositions maybe administered every 3 to 4 days, every week, or once every two weeks depending on half-life and clearance rate of the particular formulation. Normal dosage amounts may vary from 0.1 to 100,000 micrograms, up to a total dose of about 1 g, depending upon the route of administration. Guidance as to particular dosages and methods of delivery is provided in the literature and generally available to practitioners in the art. Those skilled in the art will employ different formulations for nucleotides than for proteins or their inhibitors. Similarly, delivery of polynucleotides or polypeptides will be specific to particular cells, conditions, locations, etc. For the prevention or treatment of disease, the appropriate dosage of an anti-tumor agent herein will depend on the type of disease to be treated, as defined above, the severity and course of the disease, whether the agent is administered for preventive or therapeutic purposes, previous therapy, the patient's clinical history and response to the agent, and the discretion of the attending physician. The agent is suitably administered to the patient at one time or over a series of treatments. Animal experiments provide reliable guidance for the determination of effective doses for human therapy. Interspecies scaling of effective doses can be performed following the principles laid down by Mordenti, J. and Chappell, W. "The use of interspecies scaling in toxicokinetics" in *Toxicokinetics and New Drug Development*, Yacobi *et al.*, eds., Pergamon Press, New York 1989, pp. 42-96. For example, depending on the type and severity of the disease, about 1 g/kg to 15 mg/kg (e.g., 0.1-20 mg/kg) of an antitumor agent is an initial candidate dosage for administration to the patient, whether, for example, by one or more separate administrations, or by continuous infusion. A typical daily dosage might range from about 1 g/kg to 100 g/kg or more, depending on the factors mentioned above. For repeated administrations over several days or longer, depending on the condition, the treatment is sustained until a desired suppression of disease symptoms occurs. However, other dosage regimens may be useful. The progress of this therapy is easily monitored by conventional techniques and assays. Guidance as to particular dosages and methods of delivery is provided in the literature; see, for example, U.S. Pat. Nos.

4,657,760; 5,206,344; or 5,225,212. It is anticipated that different formulations will be effective for different treatment compounds and different disorders, that administration targeting one organ or tissue, for example, may necessitate delivery in a manner different from that to another organ or tissue. Therapies may be designed to utilize RET-A-MODULIN cytotoxic properties. In

- 5 particular, therapies to enhance RET-A-MODULIN expression or administration of said polypeptides are useful in promoting inhibition or death of cancerous cells. Cytotoxic reagents may include, without limitation, full length or fragment RET-A-MODULIN polypeptides, mRNA, or any compound, which increases RET-A-MODULIN biological activity.

- Another therapeutic approach within the invention involves administration of RET-A-
- 10 MODULIN therapeutic compositions (polynucleotide, antibody, small molecule agonist or recombinant RET-A-MODULIN polypeptide), either directly to the site of a desired target cell or tissue (for example, by injection) or to a site where the composition will be further directed to the target cell or tissue, or systemically (for example, by any conventional recombinant protein administration technique). The dosage of RET-A-MODULIN depends on a number of factors,
- 15 including the size and health of the individual patient, but, generally, between 0.1 mg and 100 mg inclusive is administered per day to an adult in any physiologically acceptable formulation.

- In another embodiment, RET-A-MODULIN polypeptides and nucleic acid sequences find diagnostic use in the detection or monitoring of conditions involving aberrant levels of apoptosis. For example, decreased expression of RET-A-MODULIN may be correlated with decreased
- 20 apoptosis in humans. Accordingly, a decrease or increase in the level of RET-A-MODULIN production may provide an indication of a deleterious condition. Levels of RET-A-MODULIN expression may be assayed by any standard technique such as Northern blot analysis and RT-PCR in biopsy specimen.

- These embodiments comprise methods for detection of RET-A-MODULIN-mediated
- 25 proliferation inhibition and apoptosis including *in vitro* activity tests of RET-A-MODULIN or other proteins of the invention or fragments thereof, further cellular proliferation assays, and cellular apoptosis/necrosis assays. Specific examples of apoptosis assays are also provided in the following references. Assays for apoptosis in lymphocytes are disclosed by Noteborn et al., US Patent 5,981,502, 1999, Li *et al.*, "Induction of apoptosis in uninfected lymphocytes by HIV-1 Tat protein", Science 268: 429-431, 1995; Gibellini *et al.*, "Tat-expressing Jurkat cells show an increased resistance to different apoptotic stimuli, including acute human immunodeficiency virus-
- 30 type 1 (HIV-1) infection", Br. J. Haematol. 89: 24-33, 1995; Martin *et al.*, "HIV-1 infection of human CD4<sup>sup</sup>.+ T cells *in vitro*. Differential induction of apoptosis in these cells." J. Immunol. 152:330-342, 1994; Terai *et al.*, "Apoptosis as a mechanism of cell death in cultured T
- 35 lymphoblasts acutely infected with HIV-1", J. Clin Invest. 87: 1710-1715, 1991; Dhein *et al.*, "Autocrine T-cell suicide mediated by APO-1/(Fas/CD95)", Nature 373: 438-441, 1995; Katsikis *et al.*, "Fas antigen stimulation induces marked apoptosis of T lymphocytes in human

- immunodeficiency virus-infected individuals", J. Exp. Med. 1815:2029-2036, 1995; Westendorp *et al.*, "Sensitization of T cells to CD95-mediated apoptosis by HIV-1 Tat and gp120", Nature 375:497, 1995; DeRossi *et al.*, Virology 198:234-244, 1994. Assays for apoptosis in fibroblasts are disclosed by: Vossbeck *et al.*, "Direct transforming activity of TGF-beta on rat fibroblasts", Int. J. Cancer 61:92-97, 1995; Goruppi *et al.*, "Dissection of c-myc domains involved in S phase induction of NIH3T3 fibroblasts", Oncogene 9:1537-44, 1994; Fernandez *et al.*, "Differential sensitivity of normal and Ha-ras transformed C3H mouse embryo fibroblasts to tumor necrosis factor: induction of bcl-2, c-myc, and manganese superoxide dismutase in resistant cells", Oncogene 9:2009-2017, 1994; Harrington *et al.*, "c-Myc-induced apoptosis in fibroblasts is inhibited by specific cytokines", EMBO J. 13:3286-3295, 1994; Itoh *et al.*, "A novel protein domain required for apoptosis. Mutational analysis of human Fas antigen", J. Biol. Chem. 268:10932-10937, 1993. In vitro cellular proliferation assays comprise cultured cells such as Jurkat, HepG2, K562, or HeLa, which are treated with RET-A-MODULIN or fragments thereof at concentration ranges for example from 0.5 to 25 ug/mL, and percent decrease in cellular proliferation is measured 24, 48, and 72 hours after treatment. Cellular apoptosis is measured using an apoptosis assay kit such as VYBRANT™ Apoptosis Assay Kit #3 (Molecular Probes). After harvesting and washing, cells are stained with a FITC-labeled anti-RET-A-MODULIN antibody and analyzed by FACS according to manufacturer's instructions. Cells will be stained with P1 or DAPI to detect apoptotic nuclei. DNA fragmentation analysis will be performed by cellular DNA extraction and Southern blot analysis using about 1 ug of DNA and hybridized with randomly primed <sup>32</sup>P-labeled chromosomal DNA from said cells, which had not been treated, with RET-A-MODULIN.

These embodiments also comprise the production of RET-A-MODULIN or other proteins of the invention or fragments thereof by subcloning of said nucleotides into an expression vector such as pCMV-neo for transfection assays, Western blot analysis to measure protein expression, and detection of RET-A-MODULIN-induced apoptosis by indirect immunofluorescence and DNA fragmentation analysis. Also included in the invention is the generation of specific antibodies against RET-A-MODULIN or other proteins of the invention or fragments thereof according to methods described in the art, wherein said antibodies can be polyclonal or monoclonal.

- RET-A-MODULIN also shares homologies with two phosphorylated matrixproteins with the human cytomegalovirus, a pathogenic herpesvirus causing complications in patients with suppressed cellular immune functions and in prenatal infections (Ruger *et al.*, J Virology 61:446-453, 1987, Koretz *et al.*, N.Engl.J.Med.314:801-805, 1986, Bowden *et al.*, N.Engl.J.Med.314:1006-1010, 1986). A preferred embodiment comprises the use of RET-A-MODULIN and fragments thereof including
- GPGPVGALSSLAQTEVTLG, EGPSVESQPYSD, EVSEEEFREGFDSDINN, TTLCQVLHAVSHQDSCPGDSSSVGKVSVLGLLHEELHGPVPGALS, GPSVESQPYSD,

CQVLHAVSH, GKVSVLGLLHEELHGPV

for vaccination against Herpesvirus infections, as well as a vaccine preparation against Herpesviruses such as human cytomegalovirus (HCMV) and Kaposi Sarcoma-Associated Herpesvirus/Human Herpesvirus 8, which preparation comprises a RET-A-MODULIN protein or

5 protein part according to the invention and optionally one or more carriers and adjuvants suitable for subunit vaccines. The use of a RET-A-MODULIN protein or protein part as defined above in a process for producing RET-A-MODULIN-specific polyclonal or monoclonal antibodies also falls within the scope of the invention. Vaccination and immunization generally refer to the introduction of a non-virulent agent against which an individual's immune system can initiate an

10 immune response, which will then be available to defend against challenge by a pathogen. The immune system identifies invading "foreign" compositions and agents primarily by identifying proteins and other large molecules that are not normally present in the individual. The foreign protein represents a target against which the immune response is made. A further example is a use of RET-A-MODULIN-specific antibodies according to the invention for passive immunization

15 against Herpesvirus infections, as well as an immunization preparation for passive immunization against Herpesvirus infections, which preparation includes RET-A-MODULIN-specific antibodies according to the invention and optionally one or more carriers and adjuvants suitable for passive immunization preparations.

As regards preparative applications, one example is the use of RET-A-MODULIN-specific

20 antibodies according to the invention in a process for isolating and/or purifying RET-A-MODULIN. Routes of administration include, but are not limited to, intramuscular, intraperitoneal, intradermal, subcutaneous, intravenous, intraarterially, intraocularly and oral as well as transdermally or by inhalation or suppository. Preferred routes of administration include intramuscular, intraperitoneal, intradermal and subcutaneous injection as described by Pachuk et

25 al., US Patent 6,235,888 (2001); see also Noteborn et al., US Patent 6,238,669 (2001), Patel et al., Diagnostic Molecular Pathology 10:95-99 (2001), and Aoki and Tosato, Leuk Lymphoma, 41:229-237 (2001), which references are hereby incorporated in their entirety.

**Proteins of SEQ ID NO:48 (Internal designation Clone 1000855165\_205-99-1-0-A5-F) and SEQ ID NO:52 (Internal designation Clone 500721700\_204-43-4-0-H10-F)**

30 The cDNA of clone 1000855165\_205-99-1-0-A5-F (SEQ ID:47) encodes the protein of SEQ ID NO:48 comprising the amino acid sequence:

MIYTMKKVHALWASVCLLLNLAPAPLNADSEEDDEEHTITDTELPPLKLMHSFCAFKADD

 NNFTSKQECLRACKKGFIQRISKGGLIKTRKRKKQRVKIAYEIIFVKNM. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:48 described

throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 1000855165\_205-99-1-0-A5-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:47 described throughout the present application also pertain to the nucleic acids included in Clone 1000855165\_205-99-1-0-A5-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:47, SEQ ID NO:48, and Clone 1000855165\_205-99-1-0-A5-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The cDNA of clone 500721700\_204-43-4-0-H10-F (SEQ ID:51) encodes the protein of SEQ ID NO:52 comprising the amino acid sequence:

MIYTMKKVHALWASVCLLLNLAPAPLNADSEEDDEHTIITDTPLPLKLMHSFCAFKSDD  
 GPKCAIMKRFFFNIFTRQCEEFYGGCEGNQNRFSLEECKKMCTREKPDFCFLEEDPGICR  
 GYITRYFYNNQTKQCERFKYGGCLGNMNNFETLEECKNICEDGPNGXQVDNYGTQLNAV  
 NNSLTPQSTKVPSTLFEFHGPSWCLTPADRGLCRANENRFYNSVIGKCRPFKYSGCGGNE  
 NNFTSKQECLRACKKGFIQRISKGGLIKTKRKRKKQRVKIAEYEEIFVKNM. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:52 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 500721700\_204-43-4-0-H10-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:51 described throughout the present application also pertain to the nucleic acids included in Clone 500721700\_204-43-4-0-H10-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:51, SEQ ID NO:52, and Clone 500721700\_204-43-4-0-H10-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:48 encodes Tifapinix. The protein of SEQ ID NO:52 encodes Tifapinix-A58S. Tifapinix-A58S differs from Tifapinix in having serine at position 58 rather than alanine (A58S) (numbered from the initiating methionine of Tifapinix). It will be appreciated that the specification, composition, and embodiments directed herein to Tifapinix also are given to be directed as well to Tifapinix-A58S. Furthermore, it will also be appreciated that in said specification, composition, and embodiments directed to any polypeptide of Tifapinix wherein said polypeptide includes alanine at position 58, that said specification, composition, and embodiments given to be directed as well to the corresponding polypeptide of Tifapinix include amino acid serine at position 58.

Tifapinix is a novel splice variant of tissue factor pathway inhibitor (TFPI-1). Tissue factor (TF) initiates the extrinsic coagulation pathway (US Patent 5,849,875; US Patent 5,106,833; US Patent 6,103,499; US Patent 5,773,251; US Patent 5,994,125, 1999, which disclosures are hereby incorporated by reference in their entirety). TFPI-1 is also known as lipoprotein associated

coagulation inhibitor (LACI), so named because of its affinity for plasma lipoprotein.

Tifapinix has novel function as described below.

TFPI-1 is a secreted trivalent Kunitz-type plasma proteinase inhibitor that negatively regulates the initiation of coagulation by producing activated factor X (FXa) feedback inhibition of the catalytic complex of activated factor VII (FVIIa) and TF. The second Kunitz domain of TFPI-1 binds and inhibits FXa, whereas the first Kunitz domain is responsible for the inhibition of FVIIa in the TF-FVIIa complex. The linker region between Kunitz domains 1 and 2 of TFPI-1 is comprised of 20 amino acids (US Patent 5,849,875 which disclosures is hereby incorporated by reference in its entirety): TRDNANRIIKTTLQKEKPDF. The function of the third Kunitz domain is unknown, although there is evidence that it contains a heparin binding site. Heparin binding site(s) have also been mapped carboxyl-terminal to the third Kunitz domain.

TFPI-1 directly inhibits FXa and, in a FXa-dependent fashion, produces feedback inhibition of the TF-FVIIa catalytic complex. TFPI-1 is the major inhibitor of the protease activity of the TF-FVIIa complex. The allosteric promotion of TF-FVIIa binding by Kunitz domain 1 on FXa binding to Kunitz domain 2 presumably is carried out at least in part through the linker region between Kunitz domains 1 and 2. The finding that the Kunitz domain 2, which binds FXa, is required for inhibition of the TF-FVIIa complex has led to the proposal that TFPI-1 inhibits TF-FVIIa by forming a quaternary TF-FVIIa-FXa-TFPI-1 complex. The formation of a quaternary complex can result from either the initial binding of TFPI-1 to FXa, with subsequent binding to the TF-FVIIa complex or, alternatively, TFPI-1 could bind directly to a preformed TF-FVIIa-FXa complex. The consequence of the formation of the quaternary complex is that TF can no longer participate in initiating coagulation.

Aside from its role in coagulation, FXa plays a role in inflammation. FXa generated by TF-FVIIa has been shown to lead to pro-inflammatory activation of vascular endothelial cells through its cleavage of protease-activated receptor 2 (PAR2) (Camerer, E et al., Proc. Natl. Acad. Sci. USA 97:5255-60 (2000) which disclosure is hereby incorporated by reference in its entirety). FXa can also elicit a pro-inflammatory cellular response by cleavage of protease-activated receptor 1 (PAR1) (Kravchenko, RM Blood 97:3109-16 (2001) which disclosure is hereby incorporated by reference in its entirety). HLA-DR-restricted macrophage expression of TF in rheumatoid synovium is believed to play a role in disease pathogenesis in part through generation of FXa (Dialynas DP et al., Arthritis and Rheumatism 41:1515-6 (1998) which disclosure is hereby incorporated by reference in its entirety).

TF is a bifunctional molecule capable of inducing both fibrin deposition and angiogenesis in cancer. Cancer patients are prone to venous thromboembolism, and this hypercoagulability favors tumor growth and metastasis. In human lung cancer, melanoma, and breast cancer, TF and vascular endothelial growth factor (VEGF) co-localize in tumor cells; a close correlation exists between TF and VEGF synthesis in tumor cell lines and with angiogenesis in vivo in a severe,

combined immunodeficient mouse model (Rickles, FR et al., *Int. J. Hematol.* 73:145-50 (2001); Wojtukiewicz MZ et al., *Thromb. Haemost.* 82:1659-62 (1999); Abdulkadir SA, et al., *Hum. Pathol.* 31:443-7 (2000); Koomagi R et al., *Int. J. Cancer* 79:19-22 (1998) which disclosures are hereby incorporated by reference in their entirety).

- 5 TF supports metastasis (Mueller BM et al., *J. Clin. Invest.* 101:1372-8 (1998); Fischer EG et al., *J. Clin. Invest.* 104:1213-21 (1999) which disclosures are hereby incorporated by reference in their entirety). Equally important for this process are (a) interactions of the TF cytoplasmic domain, which binds the mobility-enhancing actin-binding protein 280, and (b) formation of a proteolytically active TF-FVIIa complex on the tumor cell surface. In primary bladder carcinoma  
10 cells, this complex localizes to the invasive edge, in proximity to tumor-infiltrating vessels that stain intensely for TFPI-1. Tumor cell adhesion and migration was shown in vitro to be supported by interaction of TF-FVIIa with TFPI-1 immobilized heparin.

- TF antigen has been detected in all cellular elements comprising the atherosclerotic plaque. The most abundant sources of TF appear to be the macrophages and intimal smooth  
15 muscle cells located in the cap surrounding the lipid-rich necrotic core. TF antigen is also present in the medial and endothelial cells overlying the plaque. In addition to its association with vascular cells, TF antigen is also found in the extracellular matrix of the intima and in the necrotic core. This TF may come in contact with circulating blood when the plaque ruptures—the most important precipitant of acute arterial thrombosis (Taubman MB et al., *Thrombosis and Haemostasis* 82:801-  
20 5 (1999) which disclosure is hereby incorporated by reference in its entirety).

- Recently it has been shown that TFPI-1 inhibits the proliferation of basic fibroblast growth factor-stimulated endothelial cells. A truncated form of TFPI-1, containing only the first two Kunitz-type proteinase inhibitor domains, has very little antiproliferative activity, suggesting that the carboxyl-terminal region of TFPI-1 is responsible for this activity (Hembrough, TA et al., *J.*  
25 *Biol. Chem.* 276:12241-8 (2001) which disclosure is hereby incorporated by reference in its entirety). By virtue of this activity, TFPI-1 is an inhibitor of angiogenesis. Anomalous angiogenesis plays an important role in a number of pathologies, including cancer, proliferative diabetic retinopathy, and rheumatoid arthritis (Folkman, J, *Forum (Geneva)* 9(3 Suppl 3):59-62 (1999); Danis, RP et al., *Expert Opin. Pharmacother* 2:395-407 (2001); Stupack, DG et al., *Braz J.*  
30 *Med. Biol. Res.* 32:573-81 (1999) which disclosures are hereby incorporated by reference in their entirety).

- In the case of Tifapinix, alternative splicing results in the internal deletion of exon 5 comprised of 13 amino acids from the linker region between Kunitz domains 1 and 2 (Girard, TJ et al., *J. Biol. Chem.* 266:5036-41 (1991) which disclosure is hereby incorporated by reference in its  
35 entirety). The A58S amino acid substitution that distinguishes Tifapinix-A58S from Tifapinix, as well as from the canonical TFPI-1 amino acid sequence (NCBI Accession No. P10646 which disclosure is hereby incorporated by reference in its entirety), establishes that the alternative

splicing of TFPI-1 represented by Tifapinix can occur for more than one allele of TFPI-1, thereby supporting the thesis that the alternative splicing represented by Tifapinix plays a significant and unique role in TFPI-1 biology.

The resultant shortened linker region between Kunitz domains 1 and 2 is comprised of 7 amino acids: TREKPDF. The deletion also results in the generation of a novel amino acid neighborhood around the two amino acids bracketing the deletion (RE, underlined above). Tifapinix retains the capacity to bind to FXa (Kunitz domain 2), but has lost the capacity to allosterically promote binding of Kunitz domain 1 to TF-FVIIa in response to the FXa binding. As Tifapinix retains the capacity to inhibit FXa, Tifapinix therefore remains both an anti-coagulant and an anti-inflammatory. As the carboxyl terminus of Tifapinix remains intact, Tifapinix retains the capacity to inhibit angiogenesis.

Importantly however and in contradistinction to TFPI-1, by virtue of having lost the capacity to allosterically promote TF-FVIIa-binding by Kunitz domain 1, Tifapinix has lost the capacity to be recruited by TF-FVIIa for promotion of tumor cell metastasis (Mueller BM et al., J. Clin. Invest. 101:1372-8 (1998); Fischer EG et al., J. Clin. Invest. 104:1213-21 (1999) which disclosures are hereby incorporated by reference in their entirety).

In a preferred embodiment, the present invention provides for an antibody that specifically binds Tifapinix of the present invention. Further preferred is a method for making said antibody wherein said antibody recognizes a non-conformational or conformational epitope of Tifapinix. Further preferred is a method for making said antibody wherein a mouse is immunized with Tifapinix. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened for binding to Tifapinix but not to TFPI-1. Further preferred is a method of making said antibody wherein said antibody is directed to the novel linker region sequence of Tifapinix comprised of amino acids 105-111, numbered from the initiating methionine of Tifapinix, or any fragment thereof. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened by sandwich enzyme-linked immunosorbent assay (ELISA) for binding to Tifapinix but not to TFPI-1. Methods of generating said monoclonal antibody and of establishing its specificity by methods including sandwich ELISA are well known to those skilled in the art.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Tifapinix. Further preferred is a method for using said antibody diagnostically to determine the basis either for immune dysfunction or for inflammopathology. In the case of inflammopathology, of which the disease states below are representative, the level of Tifapinix expression is expected to be depressed. In the case of non-inflammatory immune dysregulation, Tifapinix status is more difficult to predict a priori. In either case, Tifapinix status is expected to facilitate diagnosis and, moreover, facilitate stratification of disease states. Furthermore, Tifapinix status may also have prognostic value. Further preferred is

a method of using said antibody diagnostically in a sandwich ELISA format to quantitate Tifapinix in plasma or other bodily fluid, including but not restricted to synovial fluid and cerebrospinal fluid, within a pathological context. Further preferred is a method of using said diagnostic assay to determine the level of Tifapinix in plasma or other bodily fluid of a patient with either

- 5 dysregulated immune function or inflammopathology wherein the immune dysfunction or inflammopathology is selected from, but not restricted to, the group consisting of: (a) Rheumatoid arthritis; (b) Atherosclerosis; (c) Inflammatory bowel disease; (d) Insulin dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Multiple sclerosis; (g) Psoriasis; (h) Allergic asthma; (i) Reperfusion injury; and (j) Stroke.

- 10 In further preferred embodiment, the present invention provides for a method of using Tifapinix to treat patients with immune dysfunction or inflammopathology. Preferred compositions comprise Tifapinix. Further preferred compositions comprise Tifapinix. Preferred formulation of said composition is that formulation compatible with the route of delivery wherein said route of delivery is selected from, but not restricted to, the group: (a) Oral; (b) Transdermal;
- 15 (c) Injection wherein injection is selected from, but not restricted to, the group consisting of: intravenous, intramuscular, subcutaneous, intra-synovial, and intra-tumoral; (d) Buccal; and (e) Aerosol.

Neovascularization plays a role in the pathogenesis of a number of diseases, including but not restricted to rheumatoid arthritis [Danis RP et al., Expert Opin. Pharmacother. 2:395-407

- 20 (2001) which disclosure is hereby incorporated by reference in its entirety].

- In a further embodiment of the invention, said composition comprised of Tifapinix is used in a method of treating said patients with immune dysfunction or inflammopathology. Further preferred is a method of treating said patients in a method of ameliorating the symptoms or pathology associated with said immune dysfunction or inflammopathology. Further preferred is a
- 25 method of treating said patients in a method of ameliorating the symptoms or pathology associated with pathogenetic engagement of the extrinsic coagulation pathway or the promotion of angiogenesis by TF. Further preferred are compositions comprised of Tifapinix used in methods of delivering to said patients an ameliorative effective amount of Tifapinix by said route of delivery. Further preferred is a method of delivering said composition comprising Tifapinix by said route of
- 30 delivery to patients with immune dysfunction or inflammopathology wherein the immune dysfunction or inflammopathology is selected from, but not restricted to, the group: (a) Rheumatoid arthritis; (b) Atherosclerosis; (c) Inflammatory bowel disease; (d) Insulin dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Psoriasis; (g) Multiple sclerosis; (h) Allergic asthma; (i) Reperfusion injury; and (j) Stroke.

- 35 In acute myocardial infarction (AMI), the monocyte TF procoagulant activity is increased and may contribute to the risk for recurrence and other thrombotic events [Ott I et al., Blood 97:3721-6 (2001) which disclosure is hereby incorporated by reference in its entirety]. In a further

embodiment of the invention, said composition comprised of Tifapinix is used in a method to treat patients with AMI. Further preferred is a method of delivering by intravenous injection an ameliorative effective amount of Tifapinix in a method to treat patients with AMI.

Studies confirm the important role of TF-mediated coagulation in the smooth muscle proliferation and neointimal thickening that follows vascular injury [Han X et al., *Arterioscler. Thromb. Vasc. Biol.* 19:2563-7 (1999); Taubman MB et al., *Thrombosis and Haemostasis* 82:801-5 (1999) which disclosures are hereby incorporated by reference in their entirety]. In a further embodiment of the invention, said composition comprised of Tifapinix is used in a method to treat patients with neointimal thickening following vascular injury, including but not restricted to that consequential to balloon-induced vascular injury. Further preferred is a method of delivering by intravenous injection an ameliorative effective amount of Tifapinix in a method to treat patients with intimal thickening following vascular injury.

Studies confirm the important role of TF engagement of the extrinsic coagulation pathway in vascular pathology. In a further embodiment of the invention, said composition comprised of Tifapinix is used in a method to treat patients with said TF-associated vascular pathology. Further preferred is a method of delivering by intravenous injection an ameliorative effective amount of Tifapinix in a method to treat patients with said vascular pathology. Further preferred is a method of delivering by intravenous injection an ameliorative effective amount of Tifapinix in a method to treat patients with said vascular pathology wherein said pathology is selected from, but not restricted to, the group consisting of: (a) Disseminated intravascular coagulation (DIC); (b) Hypercoagulability; and (c) Septic shock.

Proliferative diabetic retinopathy (PDR) remains one of the major causes of acquired blindness in developed nations. The hallmark of PDR is neovascularization, abnormal angiogenesis that may ultimately cause severe vitreous cavity bleeding and/or retinal detachment. In a further embodiment of the invention, said composition comprised of Tifapinix is used in a method to treat patients with said PDR.

In a further embodiment of the invention, said composition comprised of Tifapinix is used in a method of anti-angiogenesis or anti-metastasis to treat patients with cancer. Further preferred is a method of treating said patients in a method of ameliorating the symptoms or pathology associated with said cancer. Further preferred are compositions comprised of Tifapinix used in methods of delivering to said patients an ameliorative effective amount of Tifapinix by said route of delivery. Further preferred is a method of delivering Tifapinix by said route of delivery to patients with cancer wherein the cancer is selected from, but not restricted to, the group: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Prostatic carcinoma; (f) Hodgkin's lymphoma; (g) Non-Hodgkin's lymphoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

Tifapinix represents a uniquely valuable reagent with which to address the molecular basis for the allosteric relationship between the initial FXa binding to Kunitz domain 2 and the subsequent TF-FVIIa binding to Kunitz domain 1. That is because the lesion in Tifapinix is small and well-defined: a deletion of 13 contiguous amino acids from the linker region between Kunitz domains 1 and 2. Specifically, the relative importance of linker length and linker amino acid composition can be readily addressed. In further preferred embodiment, therefore, the present invention provides for a method of recombinant DNA manipulation of polynucleotides encoding Tifapinix to identify the critical molecular parameters for said allosteric mechanism. Methods of manipulating nucleic acid sequence, including but not restricted to site-specific mutagenesis, and expression of recombinant protein are well known to those skilled in the art.

The capacity of Tifapinix to specifically inhibit the serine protease activity of FXa makes it a very useful reagent for assessing the role either of FXa serine protease activity or more generally that of the active site of FXa in a number of activities. These activities include but are not necessarily restricted to the group:

Amplification of extrinsic coagulation, as read out in a clotting assay (Dialynas DP et al. Cellular Immunology 177:671-9 (1997) which disclosure is hereby incorporated by reference in its entirety;

Serine proteolytic cleavage of specific substrate; and

Docking with its receptor, EPR-1, expressed on vascular endothelial cells and smooth muscle cells (Nicholson AC et al., J. Biol. Chem. 271:28407-13 (1996) which disclosure is hereby incorporated by reference in its entirety).

Whereas (a) and (b) require the active site of FXa, (c) does not. Tifapinix therefore would be a discriminating reagent with which to assess the involvement of FXa active site in diverse activities. For example, Tifapinix blocks (a) and (b), but does not block (c). In further preferred embodiment, the present invention provides for a method of using Tifapinix to investigate the requirement for FXa active site, and by inference FXa, in an activity manifested by a test sample.

In further preferred embodiment, Tifapinix is used for plasmin binding and inhibition. Any suitable method may be used to test the compounds of this invention (US Patent 6,103,499, 2000). Scatchard (Ann N.Y. Acad Sci (1949) 51:660-669) described a classical method of measuring and analyzing binding, which is applicable to protein binding. This method requires relatively pure protein and the ability to distinguish bound protein from unbound. A second appropriate method of measuring  $K_{sub.D}$  is to measure the inhibitory activity against the enzyme. If the  $K_{sub.D}$  to be measured is in the 1 nM to 1  $\mu$ M range, this method requires chromogenic or fluorogenic substrates and tens of micrograms to milligrams of relatively pure inhibitor. For the proteins of this invention, having  $K_{sub.D}$  in the range 5 nM to 50 pM, nanograms to micrograms of inhibitor suffice. When using this method, the competition between the inhibitor and the enzyme substrate can give a measured  $K_{sub.i}$  that is higher than the true  $K_{sub.i}$ . Measurement

reported here is not so corrected because the correction would be very small and the any correction would reduce the K.sub.i. Here, we use the measured K.sub.i as a direct measure of KD. Tifapinix has a K.sub.D for plasmin of at most about 5nM, more preferably at most about 300 pM, and most preferably 100 pM or less. Preferably, the binding is inhibitory so that K.sub.i is the same as

5 K.sub.D. The K.sub.i of QS4 for plasmin is about 2 nM. The K.sub.i of SPI11 for plasmin is about 88 pM.

In another preferred embodiment, Tifapinix is used for pharmaceutical methods and preparations. The preferred subject of this invention is a mammal. The invention is particularly useful in the treatment of humans, but is suitable for veterinary applications, too. Herein,

10 "protection" includes "prevention", "suppression", and "treatment". "Prevention" involves administration of drug prior to the induction of disease. "Suppression" involves administration of drug prior to the clinical appearance of disease. "Treatment" involves administration of drug after the appearance of disease. In human and veterinary medicine, it may not be possible to distinguish between "preventing" and "suppressing" since the inductive event(s) may be unknown or latent, or

15 the patient is not ascertained until after the occurrence of the inductive event(s). We use the term "prophylaxis" as distinct from "treatment" to encompass "preventing" and "suppressing". Herein, "protection" includes "prophylaxis". Protection need not be absolute to be useful. Tifapinix or fragments thereof may be administered, by any means, systemically or topically, to protect a subject against a disease or adverse condition. For example, administration of such a composition

20 may be by any parenteral route, by bolus injection or by gradual perfusion. Alternatively, or concurrently, administration may be by the oral route. A suitable regimen comprises administration of an effective amount of the protein, administered as a single dose or as several doses over a period of hours, days, months, or years. The suitable dosage of a protein of this invention may depend on the age, sex, health, and weight of the recipient, kind of concurrent

25 treatment, if any, frequency of treatment, and the desired effect. However, the most preferred dosage can be tailored to the individual subject, as is understood and determinable by one of skill in the art, without undue experimentation by adjustment of the dose in ways known in the art. For methods of preclinical and clinical testing of drugs, including proteins, see, e.g., Berkow et al, eds., The Merck Manual, 15<sup>th</sup> edition, Merck and Co., Rahway, N.J., 1987; Goodman et al, eds.,

30 Goodman and Gilman's The Pharmacological Basis of Therapeutics, 8th edition, Pergamon Press, Inc., Elmsford, N.Y., (1990); Avery's Drug Treatment: Principles and Practice of Clinical Pharmacology and Therapeutics, 3rd edition, ADIS Press, LTD., Williams and Wilkins, Baltimore, Md. (1987), Ebadi, Pharmacology, Little, Brown and Co., Boston, (1985), which references are hereby incorporated in their entirety. In addition to Tifapinix, a pharmaceutical composition may

35 contain pharmaceutically acceptable carriers, excipients, or auxiliaries. See, e.g., Berker, supra, Goodman, supra, Avery, supra and Ebadi, supra.

In yet another preferred embodiment, Tifapinix or fragments thereof are used for in vitro

diagnostic methods and reagents. Tifapinix and related sequences may be applied in vitro to any suitable sample that might contain plasmin to measure the plasmin present. The assay must include a Signal Producing System (SPS) providing a detectable signal that depends on the amount of plasmin present. The signal may be detected visually or instrumentally. Possible signals

5 include production of colored, fluorescent, or luminescent products, alteration of the characteristics of absorption or emission of radiation by an assay component or product, and precipitation or agglutination of a component or product. The component of the SPS most intimately associated with the diagnostic reagent is called the "label". A label may be, e.g., a radioisotope, a fluorophore, an enzyme, a co-enzyme, an enzyme substrate, an electron-dense compound, or an agglutinable

10 particle. A radioactive isotope can be detected by use of, for example, a .gamma. counter or a scintillation counter or by autoradiography. Isotopes which are particularly useful are .sup.3 H, .sup.125 I, .sup.131 I, .sup.35 S, .sup.14 C, and, preferably, .sup.125 I. It is also possible to label a compound with a fluorescent compound. When the fluorescent-labeled compound is exposed to light of the proper wavelength, its presence can be detected. Among the most commonly used

15 fluorescent labeling compounds are fluorescein isothiocyanate, rhodamine, phycoerythrin, phycocyanin, allophycocyanin, o-phthaldehyde, and fluorescamine. Alternatively, fluorescence-emitting metals, such as .sup.125 Eu or other anthanide, may be attached to the binding protein using such metal chelating groups as diethylenetriaminepentaacetic acid or ethylenediamine-tetraacetic acid. The proteins also can be detectably labeled by coupling to a chemiluminescent

20 compound, such as luminol, isolumino, thermotropic acridinium ester, imidazole, acridinium salt, and oxalate ester. Likewise, a bioluminescent compound, such as luciferin, luciferase and aequorin, may be used to label the binding protein. The presence of a bioluminescent protein is determined by detecting the presence of luminescence. Enzyme labels, such as horseradish peroxidase and alkaline phosphatase, are preferred. There are two basic types of assays:

25 heterogeneous and homogeneous. In heterogeneous assays, binding of the affinity molecule to analyte does not affect the label; thus, to determine the amount of analyte, bound label must be separated from free label. In homogeneous assays, the interaction does affect the activity of the label, and analyte can be measured without separation. Tifapinix, as a plasmin-binding protein may be used diagnostically in the same way that an antiplasmin antibody is used. Thus, depending

30 on the assay format, it may be used to assay plasmin, or, by competitive inhibition, other substances which bind plasmin. The sample will normally be a biological fluid, such as blood, urine, lymph, semen, milk, or cerebrospinal fluid, or a derivative thereof, or a biological tissue, e.g., a tissue section or homogenate. If the sample is a biological fluid or tissue, it may be taken from a human or other mammal, vertebrate or animal, or from a plant. The preferred sample is

35 blood, or a fraction or derivative thereof. In a related embodiment, Tifapinix or fragments thereof is immobilized, and plasmin in the sample is allowed to compete with a known quantity of a labeled or specifically labelable plasmin analogue. The "plasmin analogue" is a molecule capable

of competing with plasmin for binding to Tifapinix or fragments thereof. It may be labeled already, or it may be labeled subsequently by specifically binding the label to a moiety differentiating the plasmin analogue from plasmin. The phases are separated, and the labeled plasmin analogue in one phase is quantified. In a "sandwich assay", both an insolubilized plasmin-  
5 binding agent (PBA), and a labeled PBA are employed. The plasmin analyte is captured by the insolubilized PBA and is tagged by the labeled PBA, forming a tertiary complex. The reagents may be added to the sample in any order. The PBAs may be the same or different, and only one PBA needs to comprise Tifapinix or fragments thereof according to this invention (the other may be, e.g., an antibody). The amount of labeled PBA in the tertiary complex is directly proportional  
10 to the amount of plasmin in the sample. The two embodiments described above are both heterogeneous assays. A homogeneous assay requires only that the label be affected by the binding of Tifapinix or fragments thereof to plasmin. The plasmin analyte may act as its own label if Tifapinix or fragments thereof are used as a diagnostic reagent. A label may be conjugated, directly or indirectly (e.g., through a labeled anti-Tifapinix antibody), covalently (e.g., with SPDP)  
15 or noncovalently, to the plasmin-binding protein, to produce a diagnostic reagent. Similarly, the plasmin-binding protein may be conjugated to a solid phase support to form a solid phase ("capture") diagnostic reagent. Suitable supports include glass, polystyrene, polypropylene, polyethylene, dextran, nylon, amylases, and magnetite. The carrier can be soluble to some extent or insoluble for the purposes of this invention. The support material may have any structure so  
20 long as the coupled molecule is capable of binding plasmin.

In yet another preferred embodiment, Tifapinix or fragments thereof are used for in vivo diagnostic uses. Tifapinix or fragments thereof, i.e. a Kunitz domain that binds very tightly to plasmin can be used for in vivo imaging. Radiolabeled Tifapinix may be administered to a human or animal subject, typically by injection, e.g., intravenous or arterial other means of administration  
25 such as subcutaneous, intramuscular in a quantity sufficient to permit subsequent dynamic and/or static imaging using suitable radio-detecting devices. The dosage is the smallest amount capable of providing a diagnostically effective image, and may be determined by means conventional in the art, using known radio-imaging agents as guides. Typically, the imaging is carried out on the whole body of the subject, or on that portion of the body or organ relevant to the condition or  
30 disease under study. The radiolabeled binding protein has accumulated. The amount of radiolabeled binding protein accumulated at a given point in time in relevant target organs can then be quantified. A particularly suitable radio-detecting device is a scintillation camera, such as a gamma camera. The detection device in the camera senses and records (and optional digitizes) the radioactive decay. Digitized information can be analyzed in any suitable way, many of which are  
35 known in the art. For example, a time-activity analysis can illustrate uptake through clearance of the radiolabeled binding protein by the target organs with time. The radioisotope used should preferably be pharmacologically inert, and the quantities administered should not have substantial

physiological effect. The binding protein may be radio-labeled with different isotopes of iodine, for example <sup>123</sup>I, <sup>125</sup>I, or <sup>131</sup>I (see, for example, U.S. Pat. No. 4,609,725). The amount of labeling must be suitably monitored.

- In applications to human subjects, it may be desirable to use radioisotopes other than <sup>125</sup>I for labeling to decrease the total dosimetry exposure of the body and to optimize the detectability of the labeled molecule. Considering ready clinical availability for use in humans, preferred radio-labels include: <sup>99m</sup>Tc, <sup>67</sup>Ga, <sup>68</sup>Ga, <sup>90</sup>Y, <sup>111</sup>In, <sup>113m</sup>In, <sup>123</sup>I, <sup>186</sup>Re, <sup>188</sup>Re, or <sup>211</sup>At. Radiolabeled protein may be prepared by various methods. These include radio-halogenation by the chloramine-T or lactoperoxidase method and subsequent purification by high pressure liquid chromatography, for example, see Gutkowska et al in "Endocrinology and Metabolism Clinics of America 16 (1):183, 1987. Other methods of radiolabeling can be used, such as IODOBEADS.TM. Tifapinix or fragments thereof may also be used to purify plasmin from a fluid, e.g., blood. For this purpose, it is preferably immobilized on an insoluble support. Such supports include those also useful in preparing solid phase diagnostic reagents. Proteins can be used as molecular weight markers for reference in the separation or purification of proteins.

These embodiments also relate to isolation, purification and production of antibodies wherein antibodies can be polyclonal or monoclonal as described (US Patent 6,171,587 B1, 2000), hereby enclosed in their entirety.

- Another preferred embodiment relates to the use of Tifapinix and Kunitz domains thereof for the inhibition of kallikrein activity. Kallikreins are serine proteases found in both tissues and plasma (see US Patent 5,994,125, 1999, US Patent 6,057,287, 2000) which references are hereby enclosed in their entirety). Plasma kallikrein is involved in contact-activated coagulation, fibrinolysis, hypotension, and inflammation mediated through the activities of factor XII (coagulation), pro-urokinase/plasminogen (fibrinolysis), and kininogens (hypotension and inflammation). Kallikrein cleavage of kininogens results in the production of highly potent bioactive peptides (kinins), which cause increased vascular permeability, vasodilation, bronchospasm, and pain induction. Thus, kinins mediate life-threatening vascular shock and edema associated with bacteremia (sepsis) or trauma, asthma, and inflammatory and neurogenic pain associated with tissue injury, and edema in C1-inhibitor-deficient diseases (hereditary angioedema). Tifapinix, as a protease inhibitor, and fragments thereof said Kunitz domains, prevent the cleavage of kallikrein and thus the release of said kinins.

- Tifapinix may be used for any of the foregoing purposes. Methods for production using eukaryotic and prokaryotic expression systems have been reported previously and are well known in the art (US Patent 6,103,500, 2000; PCT WO 95/18830). For example, Tifapinix or fragments thereof, whereas preferred fragments comprise said Kunitz domains, preferably Kunitz domain three, may be produced by any conventional technique including (i) nonbiological synthesis by

sequential coupling of component amino acids, (ii) production by recombinant DNA techniques in a suitable host cell such as bacterial, insect- or mammalian cells, (iii) removal of undesired sequences from LACI and in coupling of synthetic replacement sequences (US patent 5,994,125, 1999, hereby incorporated in its entirety).

**5 Protein of SEQ ID NO:50 (Internal designation Clone 588098\_184-11-4-0-H4-F)**

The cDNA of Clone 588098\_184-11-4-0-H4-F (SEQ ID NO:49) encodes the protein of SEQ ID NO:50 comprising the amino acid sequence

MPSSVSWGILLLAGLCCLVPVSLGTKADTHDEILEGLNFNLTEIPEAQIHEGFQELLRTLNQ  
PDSQLQLTTGNGLFLSEGLKLVDFKLEDVKKLYHSEAFVNFVDTEEAKKQINDYVEKGT

AAGAMFLEAIPMSIPPEVKFNKPFVFLMIDXNTKSPLFMGKVVNPTQK. Accordingly it will  
be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:50 described  
15 throughout the present application also pertain to the polypeptides encoded by the nucleic acids  
included in Clone 588098\_184-11-4-0-H4-F. In addition, it will be appreciated that all  
characteristics and uses of the polynucleotides of SEQ ID NO:49 described throughout the present  
application also pertain to the nucleic acids included in Clone 588098\_184-11-4-0-H4-F. A  
preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:49,  
20 SEQ ID NO:50, and Clone 588098\_184-11-4-0-H4-F. Also preferred are polypeptide fragments  
having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:50 encodes CrypAAT, a splice variant of alpha-1-antitrypsin (antitrypsin) with novel function. In CrypAAT, internal splicing within exon 2 leaves the signal sequence intact but results in an N-terminal deletion of 67 amino acids from the mature protein.

25 This deletion extends from the disordered N-terminus through helix A and into helix B (Stein, PE et al., Nature Structural Biology 2:96-113 (1995) which disclosure is hereby incorporated by reference in its entirety). The Met-Ser active site near the C-terminus is intact.

Antitrypsin is synthesized primarily by hepatocytes and is the most abundant proteinase inhibitor in human plasma. Although it diffuses through all organs, and inhibits a large number of  
30 proteases, its primary function is in the lung parenchyma, where it protects alveolar tissue from damage by neutrophil elastase, a serine protease released in the course of an inflammatory response. Elastases are defined by their ability to cleave elastin, the matrix protein that gives tissues the property of elasticity. If left uncontrolled, neutrophil elastase leads to excessive inflammation and progressive emphysema. Individuals with antitrypsin deficiency have at least a  
35 20-fold increase risk of developing emphysema.

Antitrypsin is a member of the serpin (serine protease inhibitor) supergene family. The primary function of most of the serpins is the regulation of proteolytic enzymes under both

physiological and pathological conditions. On the basis of strong sequence similarities, a number of proteins with no known inhibitory activity have been classified as serpins. For example, thyroxine binding globulin (TBG) and corticosteroid binding globulin (CBG) serve as transporters of lipophilic hormones, and angiotensinogen is a peptide hormone precursor (Janciauskiene, S, Biochimica et Biophysica Acta.1535:221-35 (2001) which disclosure is hereby incorporated by reference in its entirety).

Serpins are competitive, irreversible inhibitors of serine proteases. Serpins have a common molecular design based on a five-stranded beta-sheet A and the reactive loop arising from it, that presents a peptide sequence to the target proteinase. The function of antitrypsin as a proteinase inhibitor depends on its undergoing conformational change when it binds to neutrophil elastase. This change involves the insertion of the cleaved reactive loop as the 4<sup>th</sup> strand in its beta-sheet A, and deactivates neutrophil elastase by swinging it from the top to the bottom of the antitrypsin molecule (described as a mousetrap action) (Parmar, JS et al., Journal of the Royal College of Physicians of London 34:295-300 (2000) which disclosure is hereby incorporated by reference in its entirety). A complex 'shutter' domain is responsible for maintaining the usual, closed state of beta-sheet A (Stein, PE et al., Nature Structural Biology 2:96-113 (1995); Gils, A et al. Thromb. Haemost. 80:531-41 (1998) which disclosures are hereby incorporated by reference in their entirety).

By virtue of conformational perturbation imposed on the protein by the novel splicing event, CrypAAT is without proteinase inhibitory function. CrypAAT retains its susceptibility to cleavage by neutrophil elastase, however. It also retains its susceptibility to cleavage by a number of non-target proteinases, such as gelatinase B (MMP-9). Unlike antitrypsin, therefore, CrypAAT functions as a proteinase substrate. Cleavage of CrypAAT by neutrophil elastase and the non-target proteinases generates a 4 kDa C-terminal fragment of 36 residues, which on cleavage remains non-covalently bound to the cleaved CrypAAT.

CrypAAT plays a number of diverse physiological roles as a proteinase substrate (Janciauskiene, S, Biochimica et Biophysica Acta 1535:221-35 (2001) which disclosure is hereby incorporated by reference in its entirety). Cleaved CrypAAT contributes to the later phase of polymorphonuclear leukocyte infiltration and is a potent chemoattractant for monocytes. The isolated C-terminal fragment of CrypAAT can associate with extracellular matrix proteins such as collagen and/or laminin-1 and, in so doing, play an important role in protecting these proteins from inappropriate enzyme digestion. The C-terminal fragment of CrypAAT also exerts significant effects on cellular lipid catabolism and proinflammatory activation, by activating peroxisome proliferator-activated receptors (PPARs), transcription factors that recently have been proposed to regulate genes for lipid metabolism and proinflammatory proteins.

CrypAAT has also been implicated in several pathologies, namely atherosclerosis and cancer. The C-terminal cleavage fragment of CrypAAT is a component of atherosclerotic plaque,

located specifically in the fibrous cap near the necrotic core. CrypAAT plays a role in atherosclerosis as a protease substrate and a reservoir of physiologically active peptide degradation products. CrypAAT-positive adenocarcinomas of colon and lung have a worse prognosis than CrypAAT-negative ones. Recent studies provide good experimental evidence that the C-terminal  
5 fragment of CrypAAT generated by matrix metalloproteinases (MMPs) enhances tumor growth and invasiveness in vivo.

Contrary to previous dogmas, it is now well established that brain cells can produce cytokines and chemokines, and can express adhesion molecules that enable an in situ inflammatory reaction. Brain ischemia and trauma elicit robust inflammation. The accumulation  
10 of neutrophils early after brain injury is believed to contribute to the degree of brain tissue loss.

In a preferred embodiment, the present invention provides for an antibody that specifically binds CrypAAT of the present invention. Further preferred is a method for making said antibody wherein said antibody recognizes a non-conformational or conformational epitope of CrypAAT.

Further preferred is a method for making said antibody wherein a mouse is immunized  
15 with CrypAAT. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened for binding to CrypAAT but not to antitrypsin. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened by enzyme-linked immunosorbent assay (ELISA) for binding to CrypAAT but not to antitrypsin. Further preferred is a method wherein said antibody is screened for the capacity to sterically or allosterically abrogate  
20 the protease susceptibility of CrypAAT. Further preferred is a method wherein said antibody is screened for the capacity to sterically or allosterically abrogate the neutrophil elastase or gelatinase susceptibility of CrypAAT. Methods of generating said monoclonal antibody and of establishing its specificity by methods including ELISA are well known to those skilled in the art. Methods of screening said antibody for the capacity to abrogate the protease susceptibility of CrypAAT are  
25 well known to those skilled in the art and include, but are not limited to: contacting the antibody with CrypAAT, incubating the antibody-CrypAAT complex with neutrophil elastase or gelatinase, and following proteolytic generation of the 4 kDa carboxyl fragment by denaturing polyacrylamide gel electrophoresis.

In a preferred embodiment, the present invention provides for a method of contacting said  
30 antibody and specifically binding it with CrypAAT. Further preferred is a method for using said antibody diagnostically to determine the basis either for immune dysfunction or for inflammopathology. Further preferred is a method of using said antibody diagnostically in a sandwich ELISA format to quantitate CrypAAT in plasma or other bodily fluid, including but not restricted to synovial fluid and cerebrospinal fluid, within a pathological context. Further  
35 preferred is a method of using said diagnostic assay to determine the level of CrypAAT in plasma or other bodily fluid of a patient with either dysregulated immune function or inflammopathology wherein the immune dysfunction or inflammopathology is selected from, but not restricted to, the

group consisting of: (a) Rheumatoid arthritis; (b) Atherosclerosis; (c) Inflammatory bowel disease; (d) Insulin dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Multiple sclerosis; (g) Psoriasis; (h) Allergic asthma; (i) Acute myocardial infarction; (j) Septic shock; (k) Reperfusion injury; and (l) Stroke.

- 5 In further preferred embodiment, the present invention provides for a method of contacting and specifically binding to CrypAAT said antibody having the capacity to abrogate the proteolytic susceptibility, including but not restricted to that of neutrophil elastase and gelatinase, of CrypAAT. Further preferred is a method of using said antibody in contact with CrypAAT as a therapeutic for patients with either immune dysfunction or inflammopathology. Preferred
- 10 compositions comprise said CrypAAT antibody or fragments or derivatives thereof. Preferred formulation of said composition is that compatible with the route of delivery wherein said route of delivery is selected from, but not restricted to, the group: (a) Oral; (b) Transdermal; (c) Injection; (d) Buccal; and (e) Aerosol.

- In further preferred embodiment, the present invention provides for a method of contacting
- 15 and specifically binding to CrypAAT said antibody having the capacity to abrogate the proteolytic susceptibility, including but not restricted to that of neutrophil elastase and gelatinase, susceptibility of CrypAAT. Further preferred is a method for using said CrypAAT antibody to treat patients with immune dysfunction or inflammopathology. Further preferred is a method of treating said patients with said CrypAAT antibody in a method of ameliorating the symptoms or
- 20 pathology associated with immune dysfunction or inflammopathology. Said CrypAAT antibody ameliorates the symptoms or pathology associated with immune dysfunction or inflammopathology by suppressing proteolytic generation of bioactive fragments of CrypAAT, including but not restricted to the 4 kDa carboxyl fragment. Further preferred is a method of delivering to said patients an ameliorative effective amount of said CrypAAT antibody. Further
- 25 preferred is a method of delivering to said patients an ameliorative effective amount of said CrypAAT antibody by injection. Further preferred is a method of delivering to said patients with immune dysfunction or inflammopathology an ameliorative effective amount of said CrypAAT antibody wherein said immune dysfunction or inflammopathology is selected from, but not restricted to, the group: (a) Rheumatoid arthritis; (b) Atherosclerosis; (c) Inflammatory bowel
- 30 disease; (d) Insulin dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Psoriasis; (g) Multiple sclerosis; (h) Allergic asthma; (i) Acute myocardial infarction; (j) Septic shock; (k) Reperfusion injury; and (l) Stroke.

- Further preferred is a method of contacting and specifically binding said antibody with CrypAAT in a method of transdermal contact to ameliorate the symptoms or pathology of
- 35 psoriasis. Further preferred are compositions comprised of said CrypAAT antibody used in methods of contacting the psoriatic lesion with an ameliorative effective amount of said CrypAAT antibody by injection or transdermal contact at the site of the lesion.

Further preferred is a method of contacting and specifically binding said antibody with CrypAAT in a method to ameliorate the symptoms or pathology of allergic asthma. Preferred route of delivery is aerosol. Further preferred are compositions comprised of said CrypAAT antibody used in methods of contacting asthmatic tissue with an ameliorative effective amount of  
5 said CrypAAT antibody by aerosol.

Further preferred is a method of contacting and specifically binding said antibody with CrypAAT in a method to ameliorate the symptoms or pathology of allergic rhinitis (hayfever). Preferred route of delivery is aerosol. Further preferred are compositions comprised of said CrypAAT antibody used in methods of contacting inflamed nasal tissue with an ameliorative  
10 effective amount of said CrypAAT antibody by aerosol.

In a further embodiment, the present invention provides for said CrypAAT antibody to be used in a method to suppress acute inflammation. Further preferred is a method to use said CrypAAT antibody to suppress inflammation associated with wound healing. Further preferred are compositions comprised of said antibody used in methods of contacting a wound or injured tissue  
15 with an ameliorative effective amount by injection or transdermal contact at the site of the wound.

In further preferred embodiment, the present invention provides for a method of contacting and specifically binding to CrypAAT said antibody having the capacity to abrogate the proteolytic susceptibility, including but not restricted to that of neutrophil elastase and gelatinase, susceptibility of CrypAAT. Further preferred is a method of treating cancer patients with said  
20 CrypAAT antibody in a method of ameliorating the symptoms or pathology associated with the cancer. Said CrypAAT antibody ameliorates the symptoms or pathology associated with cancer (including but not restricted to metastasis and invasiveness) by suppressing proteolytic generation of bioactive fragments of CrypAAT, including but not restricted to the 4 kDa carboxyl fragment. Further preferred is a method of delivering to said patients an ameliorative effective amount of said  
25 CrypAAT antibody by said route of delivery. Preferred route of delivery is intravenous or intra-tumoral injection. Further preferred is a method of delivering to said patients with cancer an ameliorative effective amount of said CrypAAT antibody wherein said cancer is selected from, but not restricted to, the group: (a) Melanoma; (b) Breast carcinoma; (c) Lung carcinoma; (d) Colon carcinoma; (e) Hodgkin's lymphoma; (f) Non-Hodgkin's lymphoma; (g) Prostatic  
30 carcinoma; (h) Pancreatic carcinoma; (i) Uterine carcinoma; (j) Ovarian carcinoma; (k) Testicular carcinoma; (l) Renal carcinoma; (m) Hepatic carcinoma; and (n) Lung non-small-cell carcinoma.

In a further embodiment, the present invention provides for said CrypAAT antibody to be used in a method of preclinical pharmacology in animal models of disease, including but not restricted to those of immune dysfunction, inflammopathology, and cancer.

35 Further preferred is a method in which said CrypAAT antibody is used in a rodent or primate model of human immune dysfunction or inflammopathology to optimize the therapeutic efficacy of said CrypAAT antibody. Further preferred is a method in which said CrypAAT

antibody is used in a rodent or primate model of human immune dysfunction or inflammopathology wherein said immune dysfunction or inflammopathology is selected from but not restricted to the group: (a) Rheumatoid arthritis; Atherosclerosis; Inflammatory bowel disease; Insulin dependent diabetes (Type 1 diabetes); Systemic lupus erythematosus; Psoriasis;

5 Multiple sclerosis; Allergic asthma; Acute myocardial infarction; Septic shock; Reperfusion injury; and Stroke.

- Further preferred is a method in which said CrypAAT antibody is used in a mouse model of human cancer to optimize the therapeutic efficacy of said CrypAAT antibody. Further preferred is a method in which said CrypAAT antibody is used in a xenogeneic mouse model of human
- 10 leukemia. Preferred route of delivering said composition comprised of CrypAAT antibody includes but is not restricted to intravenous injection and implanted pump. Further preferred is a method in which said CrypAAT antibody is used in a xenogeneic mouse model of human leukemia engrafted with primary leukemia cells obtained from patients (Dialynas, DP et al., Blood 97:3218-25 (2001) which disclosure is hereby incorporated by reference in its entirety) wherein the
- 15 leukemia is selected from but not restricted to the group: (a) Childhood T lymphocyte acute lymphoblastic leukemia (Pediatric T-ALL); (b) Adult T lymphocyte acute lymphoblastic leukemia (Adult T-ALL); (c) B lymphocyte acute lymphoblastic leukemia (B-ALL); (d) Acute myeloid leukemia (AML); (e) Chronic lymphocytic leukemia (CLL); and (f) Multiple myeloma.

- In a further embodiment, the present invention provides for the use of said CrypAAT
- 20 antibody in a method to abrogate proteolytic generation of the bioactive 4 kDa fragment of CrypAAT in in vitro cell cultures using human serum. Further preferred is a method of contacting and specifically binding said CrypAAT antibody to CrypAAT in culture to block in situ proteolytic generation of the bioactive 4 kDa carboxyl fragment from CrypAAT introduced into culture by human serum. Further preferred is a method of contacting and specifically binding said CrypAAT
- 25 antibody immobilized on a resin to CrypAAT to deplete CrypAAT from human serum samples by immunoaffinity chromatography.

- In a further embodiment, the present invention provides for the screening of test compounds for the capacity to specifically bind to CrypAAT and block the proteolytic generation of the 4 kDa carboxyl fragment by proteases including but not restricted to neutrophil elastase and
- 30 gelatinase. Further preferred are said test compounds that specifically bind to either a non-conformational or conformational site on CrypAAT. Further preferred are said test compounds that block said proteolytic cleavage of CrypAAT either sterically or allosterically. Further preferred is a method of screening said test compounds for the capacity to block cleavage within the active site of CrypAAT by neutrophil elastase or non-target proteinase and so generate the 4
- 35 kDa carboxyl fragment. Methods of screening said test compound for the capacity to abrogate the protease susceptibility of CrypAAT are well known to those skilled in the art and include, but are not limited to: contacting the test compound with CrypAAT, incubating the test compound-

CrypAAT complex with neutrophil elastase or gelatinase, and following proteolytic generation of the 4 kDa carboxyl fragment by denaturing polyacrylamide gel electrophoresis.

Preferred formulations of said compound are those selected from, but not restricted to, formulations amenable to the routes of delivery selected from the group: (a) Oral;

- 5 (b) Transdermal; (c) Injection; (d) Buccal; and (e) Aerosol.

Compounds found to block the cleavage of CrypAAT within its active site by elastase or non-target proteinase are used in in vivo and in vitro methods analogous to those described above for CrypAAT antibody.

**Protein of SEQ ID NO:54 (Internal designation Clone 789749\_182-14-3-0-C12-F)**

- 10 The cDNA of clone 789749\_182-14-3-0-C12-F (SEQ ID NO:53) encodes the protein of SEQ ID NO:54 comprising the amino acid sequence:

MHFCGGTLISPEWVLTAAHCLEKSPRPSSYKVLGAHQEVNLEPHVQEIEVSRLFLEPTRK  
DIALCLKLSSPAVITDKVIPACLPSPNYVVADRTECFITGWGETQGTFGAGLLKEAQLPVIEN  
KVCNRYEFLNGRVQSTELCAGHLAGGTDSCQGDSGGPLVCFEKDKYILQGVTSWGLGCA  
15 RPNKPGVYVRVSRFVTWIEGVMRNN.

- Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:54 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 789749\_182-14-3-0-C12-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:53 described throughout the present application also pertain to the nucleic acids included in Clone 789749\_182-14-3-0-C12-F. Also preferred are fragments having a biological activity as described therein and the polynucleotides encoding the fragments.
- 20

- The protein of SEQ ID NO:54 encodes Plasminute, a variant of plasmin resulting from alternative transcription initiation within the plasminogen gene. Plasminute has novel function as described below.
- 25

- The terminal event in activation of the human fibrinolytic system is generation of the enzyme plasmin, a serine protease possessing a variety of functional properties, the most notable of which is clearance by proteolytic degradation of fibrin deposits. Plasmin is formed upon activation of its zymogen, plasminogen, as a result of cleavage of a single peptide bond. This latter event is catalyzed by serine proteases with narrow specificity, termed plasminogen activators. Urokinase-type plasminogen activator and tissue-type plasminogen activator act directly; streptokinase acts indirectly. In its capacity as a serine protease, plasmin functions to dissolve the fibrin clot. Each of these plasminogen activators is commercially available and is indicated for the treatment of acute vascular diseases such a myocardial infarct, stroke, pulmonary embolism, deep vein thrombosis, peripheral arterial occlusion, and other venous thromboses (US Patent 5,753,486; "Human tissue plasminogen activator;" which disclosure is hereby incorporated by reference in its entirety). Collectively, these diseases account for major health hazards and risks.
- 30
- 35

In its capacity as a serine protease, plasmin also plays a role in normal processes involving cell migration in tissue remodeling. In this regard, plasmin is believed to function in processes in which cell movement is essential, such as macrophage invasion in inflammation, angiogenesis, and keratinocyte accumulation after wound healing. Furthermore, plasmin has also been strongly implicated as an important mediator in pathological processes of cell migration that are involved in tumor cell growth (plasmin can activate growth factors) and invasion of surrounding tissue and, perhaps, metastases. Involvement of plasmin in these latter processes is supported by the ability of plasmin to degrade extracellular matrix proteins directly, such as proteoglycans, fibronectin, laminin, and type IV collagen, and/or be indirectly responsible for the degradation of matrix proteins through activation of metalloprotease zymogens, such as stromolysin and procollagenase. As a result of degradation of the extracellular matrix, cell migration into surrounding areas becomes more facile (Castellino, FJ in *Molecular Basis of Thrombosis and Hemostasis*, High, KA & Roberts, HR, editors, New York, pp 495-515 (1995) which disclosure is hereby incorporated by reference in its entirety).

Plasminogen is synthesized by endothelial cells as an 810-residue single chain glycoprotein, from which is excised a 19-residue signal peptide during secretion. Plasminogen is converted to plasmin as a result of activator-catalyzed cleavage of the Arg561-Val562 peptide bond (numbered from the amino-terminal glutamic acid residue of secreted plasminogen). The resulting plasmin contains a heavy chain, originating from the amino-terminus of plasminogen, doubly disulfide-linked to a light chain. This latter region, containing the carboxy-terminus of plasminogen, is homologous to serine proteases such as trypsin and elastase. The heavy chain of plasmin consists of five repeating triple-disulfide-linked peptide regions, about 80 amino acid residues in length, termed kringles, that are responsible in part for interactions of plasmin with inhibitors (Castellino, FJ et al., Ciba Found. Symp. 212:46-60 (1997) which disclosure is hereby incorporated by reference in its entirety).

The gene for human plasminogen spans about 52.5 kilobases of DNA and consists of 19 exons separated by 18 introns (Petersen, TE et al., J. Biol. Chem. 265:6104-11 (1990) which disclosure is hereby incorporated by reference in its entirety).

Plasminogens exist in about three different forms in solution, as determined by laser light scattering experiments and NMR. Three truncated forms of plasminogen have been described. Removal of the amino-terminal domain yields a shorter proenzyme (Lys-plasminogen) that is more efficiently activated than the parent (Glu-plasminogen). Further cleavage using the enzyme elastase removes the amino-terminal domain and four kringle domains leaving miniplasminogen. Miniplasminogen is activatable by urokinase to the enzyme miniplasmin with fibrinolytic activity equivalent to that of plasmin. The most striking functional difference of miniplasmin is its relative resistance to inhibition by the primary plasmin inhibitor, alpha-2-antiplasmin, probably reflecting the absence of kringle domain 1, which is thought to facilitate primary interaction of plasmin with

the inhibitor (Moroz, LA, Blood, 58:97-104 (1981) which disclosure is hereby incorporated by reference in its entirety).

A functionally active human microplasminogen without kringle structures was produced by incubation of plasminogen with urokinase-free plasmin at alkaline pH. Microplasminogen can be activated by urokinase and streptokinase to catalytically active microplasmin. Microplasmin consists of two polypeptide chains connected by disulfide bonds: one is the intact light chain, and the other is a peptide of 31 residues from the carboxyl-terminal portion of the heavy chain (Shi, G-Y et al., J. Biol. Chem. 263:17071-5 (1988) which disclosure is hereby incorporated by reference in its entirety).

It is significant that the formation of plasminogen fragments such as miniplasminogen-like molecules has been observed under some pathophysiological conditions. Of particular note is a report that synovial fluid in acute inflammatory arthritis (including rheumatoid arthritis), unlike that of acute non-inflammatory arthritis (including osteoarthritis), contains low molecular weight fragments of plasminogen with the properties of miniplasminogen (Moroz, LA et al., Thrombosis Research 43:417-24 (1986) which disclosure is hereby incorporated by reference in its entirety). Whether neutrophil elastase or other mechanisms are responsible for their generation, the presence in inflamed joints of molecules with properties of miniplasminogen indicates a potential for their participation in inflammatory events where plasmin activity has been implicated, as in the activation of procollagenase to collagenase in rheumatoid synovium, but where the inhibitory activity of alpha-2-antiplasmin has been invoked as an obstacle to such a view. However, the ability of molecules such as miniplasmin to escape such inhibition suggests the possibility that generation of miniplasmin might lead to activation of procollagenase, or destroy joint structural proteins directly.

Plasminute is the product of alternative transcription initiation within the plasminogen gene. Transcription initiates within intron N (at least 1036 nucleotides upstream of exon XV) and proceeds through the remainder of the plasminogen gene (Petersen, TE et al., J. Biol. Chem. 265:6104-11 (1990); NCBI Accession No. AL109933.25 which disclosures are hereby incorporated by reference in their entirety). Splicing occurs normally between transcribed exons XV to XIX. Translation initiates within exon XV and is carried out in the plasminogen open reading frame. Plasminute represents the carboxyl-terminal fragment of plasminogen corresponding to amino acids 585 to 790 (numbered from the amino-terminal glutamic acid residue of secreted plasminogen).

Importantly, Plasminute is a variant of plasmin distinguished by the novel manner in which its protease activity escapes regulation. Plasminute retains the catalytic triad of plasmin (His603, Asp646, Ser741, numbered from the amino-terminal glutamic acid residue of secreted plasminogen). Plasminute manifests constitutive protease activity, circumventing the requirement for proteolytic activation by virtue of its translation initiating downstream of the cleavage site

involved in the conversion to plasmin from plasminogen (amino acids 561-562 of secreted plasminogen, numbered from the amino terminal glutamic acid residue). In addition, the protease activity of Plasminute is relatively resistant to inhibition by the primary plasmin inhibitor, alpha-2-antiplasmin, by virtue of its translation initiating downstream of the plasminogen kringle domains.

5 In a preferred embodiment, the present invention provides for a method of contacting Plasminute with a blood clot in patients with acute vascular disease. The advantage of Plasminute over plasminogen activators is two-fold: 1) it circumvents the necessity to generate plasmin within the patient and therefore is more direct and controllable; and 2) it is not immediately neutralized by excess alpha-2-antiplasmin, as is the case for most of the plasmin generated through exogenously  
10 administered activator (US Patent 5,753,486; "Human tissue plasminogen activator;" which disclosure is hereby incorporated by reference in its entirety). Preferred compositions comprise Plasminute. Preferred mode of administration is intravenous injection.

In further preferred embodiment, the present invention provides for a method of contacting Plasminute with a blood clot in patients with diseases having an etiological basis pointing to either  
15 a partial or, in severe cases, total occlusion of a blood vessel by a blood clot—thrombus or thromboembolus. Further preferred is a method of contacting Plasminute with a blood clot in said patients for the purpose of dissolving said clot. Further preferred are compositions comprised of Plasminute used in methods of contacting a blood clot with an ameliorative effective amount in patients with acute vascular disease wherein the acute vascular disease is selected from, but not  
20 restricted to, the group consisting of: (a) Myocardial infarct; (b) Stroke; (c) Pulmonary embolism; (d) Deep vein thrombosis; (e) Peripheral arterial occlusion; and (f) Other venous thromboses.

Plasmin plays an important role in wound healing, including recovery from myocardial infarction, skin wounds, and arterial neointima formation. In the course of myocardial infarction, cardiomyocytes die and a process that resembles wound healing in, for instance, skin wounds and  
25 requiring plasmin occurs (Creemers E, et al., Am. J. Pathol. 156:1865-73 (2000) which disclosure is hereby incorporated by reference in its entirety). Specifically with respect to skin wounds, plasmin is required for the efficient keratinocyte migration necessary for wound closure (Romer J et al., Nat. Med. 2:287-92 (1996) which disclosure is incorporated by reference in its entirety). With respect to arterial neointima formation, plasmin is required for migration of smooth muscle  
30 cells into the necrotic center of the induced arterial wall injury (Carmeliet, P et al., J. Clin. Invest. 99:200-8 (1997) which disclosure is incorporated by reference in its entirety).

In further embodiment, the present invention provides for compositions comprised of Plasminute used in methods of promoting wound healing. Further preferred are compositions comprised of Plasminute used in methods of contacting said wound with an ameliorative effective  
35 amount wherein the wound is selected from, but not restricted to, the group consisting of: (a) Myocardial infarction; (b) Skin wound; and (c) Arterial wall injury.

The compositions and methods for treatment of acute vascular disease and wound healing

discussed above are not limited to use in humans, but can have veterinary applications as well.

Partial digestion of a protein by plasmin is frequently exploited in in vitro biochemical analysis of said protein (Bewley, TA, Biochemistry 16:209-15 (1977); Nawratil, P et al., J. Biol. Chem. 271:31735-41 (1996); Kost, C et al., Eur. J. Biochem. 236:682-8 (1996); Angeloz-Nicoud, P et al., Growth Hormone and IGF Research 8:71-75 (1998); Itoh, Y et al., J. Biochem. 128:1017-24 (2000); which disclosures are hereby incorporated by reference in their entirety). For example, partial digestion by plasmin can be useful in assigning function to specific protein domains and in mapping antigenic epitopes onto the protein. Plasminute has utility over plasmin for said biochemical analysis in that: 1) production of Plasminute does not require proteolytic activation of plasminogen; and 2) the smaller size of Plasminute makes it easier to manipulate.

Further preferred are compositions comprised of Plasminute used in methods of in vitro biochemical analysis of protein, including but not restricted to the analysis of protein function and antigenicity. Further preferred are compositions comprised of Plasminute used as part of a kit in methods of in vitro biochemical analysis of protein, including but not restricted to the analysis of protein function and antigenicity.

In a preferred embodiment, the present invention provides for an antibody that specifically binds Plasminute of the present invention. Further preferred is a method of making said antibody wherein said antibody recognizes a non-conformational or conformational epitope of Plasminute. Further preferred is a method of making said antibody wherein said antibody neutralizes the serine protease activity of Plasminute or facilitates the elimination of Plasminute from tissue.

Further preferred is a method wherein a mouse is immunized with Plasminute. Further preferred is a method wherein monoclonal antibodies from said mouse are screened for binding to Plasminute but not to plasmin or plasminogen. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened by enzyme-linked immunosorbent assay (ELISA) for binding to Plasminute but not to plasmin or plasminogen. Further preferred is a method wherein monoclonal antibodies from said mouse are screened for binding to Plasminute but not to plasmin, plasminogen, miniplasmin, miniplasminogen, microplasmin, or microplasminogen. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened by ELISA for binding to Plasminute but not to plasmin, plasminogen, miniplasmin, miniplasminogen, microplasmin, or microplasminogen. Further preferred is a method wherein said antibody is screened for the capacity to sterically or allosterically neutralize the serine protease activity of Plasminute. Further preferred is a method of humanizing said monoclonal antibody. Methods of generating said monoclonal antibody and of establishing specificity by methods including ELISA are well known to those skilled in the art. Methods of screening said antibody to neutralize the serine protease activity of Plasminute are well known to those skilled in the art and include, but are not limited to: contacting the antibody with Plasminute, incubating the antibody-Plasminute complex with a substrate of Plasminute, and following proteolytic activation of the

Plasminute substrate. Methods of humanizing said monoclonal antibody are well known to those skilled in the art.

The functionality of Plasminute is proinflammatory. Functional fragments of plasminogen at least as small as miniplasminogen have been observed in synovial fluid in acute inflammatory  
5 arthritis but not in synovial fluid in acute non-inflammatory arthritis (Moroz, LA et al., Thrombosis Research 43:417-24 (1986) which disclosure is hereby incorporated by reference in its entirety).

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Plasminute. Further preferred is a method for using said antibody diagnostically to determine the basis for inflammopathology. Further preferred is a  
10 method for using said antibody diagnostically in a sandwich ELISA format to determine the level of Plasminute in plasma or other bodily fluid, including but not restricted to synovial fluid and cerebrospinal fluid, within a pathological context. Further preferred is a method for using said antibody in a sandwich ELISA format to determine the level of Plasminute in plasma or other bodily fluid, including but not restricted to synovial fluid and cerebrospinal fluid, from normal  
15 subjects in order to establish a baseline level of Plasminute. Further preferred is a method of using said diagnostic assay to determine the level of Plasminute in plasma or other bodily fluid of a patient with inflammopathology wherein the inflammopathology is selected from, but not restricted to, the group consisting of: (a) Atherosclerosis; (b) Inflammatory bowel disease; (c) Insuline dependent diabetes mellitus (Type 1 diabetes); (d) Systemic lupus erythematosus;  
20 (e) Multiple sclerosis; Psoriasis; (f) Allergic asthma; (g) Septic shock; and (h) Reperfusion injury.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Plasminute. Further preferred is a method for using said antibody diagnostically to determine the basis for inflammatory arthritis. Further preferred is a method of using said diagnostic assay to determine the level of Plasminute in synovial fluid of a  
25 patient with acute inflammatory arthritis (a-d below) or acute non-inflammatory arthritis (e-f below). Plasminute level may be additionally useful is distinguishing the former from the latter (Moroz, LA et al., Thrombosis Research 43:417-24 (1986) which disclosure is hereby incorporated by reference in its entirety).

In a preferred embodiment, the present invention provides for a method of contacting said  
30 antibody and specifically binding it with Plasminute. Further preferred is a method of using said diagnostic assay in said sandwich ELISA format to determine the level of Plasminute in synovial fluid of a patient with acute inflammatory arthritis or acute non-inflammatory arthritis. Further preferred is a method of using said diagnostic assay to determine the level of Plasminute in synovial fluid of a patient with acute inflammatory arthritis or acute non-inflammatory arthritis  
35 wherein the arthritis is selected from, but not restricted to, the group consisting of: (a) Rheumatoid arthritis; (b) Gout; (c) Septic arthritis; (d) Reiter's syndrome; (e) Osteoarthritis; and (f) Trauma.

In a preferred embodiment, the present invention provides for a method of contacting said

antibody and specifically binding it with Plasminute. Further preferred is a method of using said antibody diagnostically in an immunohistochemistry format to determine the level of Plasminute in affected tissue in a patient presenting with inflammopathology. Further preferred is a method of using said antibody diagnostically in an immunohistochemistry format to determine the level of

- 5 Plasminute in affected tissue in a patient presenting with inflammopathology wherein said inflammopathology is selected from, but not restricted to, the group consisting of:

(a) Inflammatory arthritis; (b) Atherosclerosis; (c) Inflammatory bowel disease; (d) Insuline dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Multiple sclerosis; (g) Psoriasis; (h) Allergic asthma; (i) Septic shock; and (j) Reperfusion injury.

- 10 The components of the urokinase plasminogen activator system involved in conversion of plasminogen to plasmin are present in significantly higher amounts in malignant tumors than in normal tissue or benign tumors, and said elevated expression is related to poor prognosis for a variety of patients diagnosed with tumors including breast, prostate, lung, or colon cancer (Andreasen, PA et al., Cell. Mol. Life Sci. 57:25-40 (2000) which disclosure is hereby  
15 incorporated by reference in its entirety) (discussed in more detail below). The largest data sets correlating urokinase plasminogen activator level with patient prognosis are available for breast cancer. In the Western world, about one in every ten women will develop breast cancer. In a significant number of these patients, metastatic cells will have spread to the lymph nodes and other tissues by the time their breast tumor is diagnosed. Therefore, following surgery these patients will  
20 normally receive some kind of additional therapy aimed at reducing their risk of developing secondary cancer.

- Even for those patients whose lymph nodes are free of tumor cells (node negative), it is still important to know whether they are at high or low risk of developing secondary tumors. Measuring the levels of the components of the urokinase plasminogen activator system can assess  
25 this risk, high levels indicating a high risk of developing metastases and suggesting that patients should be treated with additional therapy. Just as elevated plasmin generation on engagement of the urokinase plasminogen activator system indicates high risk for metastases, elevated Plasminute expression by the tumor cells indicates high risk for metastases. In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with  
30 Plasminute. Further preferred is a method of using said antibody diagnostically in an immunohistochemistry format to determine the level of Plasminute in affected tissue in a patient presenting with cancer. Further preferred is a method of using said antibody diagnostically in an immunohistochemistry format to determine the level of Plasminute expressed by tumor cells in a patient presenting with cancer wherein said cancer is selected from, but not restricted to, the group  
35 consisting of: (a) Melanoma; (b) Squamous cell carcinoma of the skin; (c) Breast carcinoma; (d) Lung small-cell carcinoma; (e) Colon carcinoma; (f) Hodgkin's lymphoma; (g) Non-Hodgkin's lymphoma; (h) Prostatic carcinoma; (i) Pancreatic carcinoma; (j) Osteosarcoma; (k) Uterine

carcinoma; (l) Ovarian carcinoma; (m) Chondrosarcoma; (n) Endometrial cancer; (o) Testicular carcinoma; (p) Renal carcinoma; (q) Hepatic carcinoma; (r) Lung non-small-cell carcinoma; (s) T lymphocyte acute lymphoblastic leukemia (T-ALL); (t) B lymphocyte acute lymphoblastic leukemia (B-ALL); (u) Acute myeloid leukemia (AML); (v) Chronic lymphocytic leukemia (CLL); and (w) Multiple myeloma.

Viral hemorrhagic fevers are a group of diseases caused by viruses from four distinct families: filoviruses, arenaviruses, flaviviruses, and bunyaviruses. Virus driven expression of host Plasminute and a consequential hyperfibrinolysis may be contributory to at least some said viral pathologies. Furthermore, measuring Plasminute level may have diagnostic value in distinguishing between viruses in this group or have diagnostic value in distinguishing viruses belonging to this group from viruses not belonging to this group.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Plasminute. Further preferred is a method of using said diagnostic assay in sandwich ELISA format to determine the level of Plasminute in plasma or other bodily fluid in a patient suspected of having viral hemorrhagic fever. Further preferred is a method for using said diagnostic assay to determine the level of Plasminute in a patient infected by a virus not belonging to the group causing viral hemorrhagic fever, in order to establish a baseline level of Plasminute level in said other viral infection. Further preferred is a method of using said diagnostic assay to determine the level of Plasminute in plasma or other bodily fluid in patient suspected of having viral hemorrhagic fever when said virus is selected from, but is not restricted to, the group consisting of: (a) Ebola virus; (b) Omsk hemorrhagic fever virus; (c) Junin virus; (d) Marburg virus; (e) Crimean-Congo hemorrhagic fever virus; and (f) Dengue fever virus.

The serine protease activity of Plasminute is relatively resistant to inhibition by the primary plasmin inhibitor, alpha-2-antiplasmin, by virtue of its translation initiating downstream of the plasminogen kringle domains. In in vitro analysis of clinical samples, it is important to prevent artifactual proteolysis of the sample ex vivo, including that by plasmin or a derivative thereof. If the sample contains Plasminute, the current art of using alpha-2-antiplasmin to block said proteolysis would be inadequate. In this context, said antibody directed to Plasminute and neutralizing its serine protease activity would have utility over alpha-2-antiplasmin. In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Plasminute. Further preferred is a method of using said neutralizing anti-Plasminute antibody to block ex vivo proteolysis by Plasminute within clinical samples.

There is precedent for the expression of two alternatively spliced transcripts derived from the same gene and encoding functionally distinct protein isoforms being reciprocally modulated by cytokine. This is the case for monocyte expression of CD86, a T lymphocyte co-stimulator molecule, for example. Interferon gamma down-regulates monocyte expression of the alternatively spliced transcript encoding a truncated and interfering version of CD86 and up-

regulates the spliced transcript encoding full-length CD86 (Magistrelli, G et al., Biochem. Biophys. Res. Commun. 280:1211-5 (2001) which disclosure is hereby incorporated by reference in its entirety). It is not unreasonable to expect, therefore, that there may be cytokine modulation of transcription initiation within a gene leading to alternative transcripts encoding functionally distinct protein isoforms, as is the case for the present invention. Identification of said cytokine regulation of alternative transcription initiation within a gene would be expected to have therapeutic value and to lead to a better understanding of disease pathology.

In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with Plasminute. Further preferred is a method of using said antibody to characterize cytokine regulation of Plasminute expression by endothelial cells. Further preferred is a method of using said antibody in said sandwich ELISA to characterize cytokine regulation of Plasminute expression by endothelial cells. Further preferred is a method of using said antibody in said sandwich ELISA to characterize cytokine regulation of Plasminute expression by endothelial cells wherein the cytokine is selected from, but not restricted to, the group consisting of: (a) Interferon gamma; (b) Interleukin 17; (c) Interleukin 4; (d) Interleukin 10; (e) Interleukin 13; (f) Interleukin 15; (g) Interleukin 12; (h) Interleukin 18; (i) Interleukin 20; (j) Interleukin 21; (k) Interleukin 1 beta; (l) Interleukin 6; (m) Monocyte chemotactic protein 1 (MCP-1); (n) RANTES; (o) IP-10; (p) Vascular endothelial growth factor (VEGF); (q) Transforming growth factor beta; (r) Interleukin 8; and (s) Tumor necrosis factor alpha.

Methods of characterizing cytokine regulation of Plasminute expression by endothelial cells are well known to those skilled in the art and include, but are not limited to: incubation of endothelial cells with or without cytokine for 24-48 hours, collection of culture supernatant, and determination of Plasminute protein in the culture supernatant by sandwich ELISA.

The transcript encoding Plasminute can be readily distinguished from that encoding plasminogen and its derivatives. Further preferred therefore is a method of directly characterizing cytokine regulation of Plasminute mRNA expression by endothelial cells. Further preferred is a method of using polynucleotide comprising Plasminute to determine the level of Plasminute mRNA in endothelial cells. Further preferred is a method of using polynucleotide comprising Plasminute to determine the level of Plasminute mRNA in endothelial cells that have been incubated in the presence or absence of cytokine for 0, 2, 4, 6, 8, 12, or 24 hours. Further preferred is a method of using a Plasminute cDNA fragment encoding 5'-untranslated sequence derived from intron N as a specific probe in Northern blot analysis of said Plasminute mRNA level. Further preferred is a method of using a primer specified in Plasminute 5'-untranslated sequence derived from intron N in conjunction with a primer specified in Plasminute 3'-untranslated sequence to specifically determine said Plasminute mRNA level by reverse transcriptase-polymerase chain reaction (RT-PCR). Methods of carrying out Northern blot analysis or RT-PCR on total or poly(A)+ RNA are well known to those in the art.

The functionality of Plasminute is proinflammatory. In this context, it is significant that functional fragments of plasminogen at least as small as miniplasminogen have been observed in synovial fluid in acute inflammatory arthritis but not in synovial fluid in acute non-inflammatory arthritis (Moroz, LA et al., Thrombosis Research 43:417-24 (1986) which disclosure is hereby incorporated by reference in its entirety). Said neutralizing anti-Plasminute antibody would be expected to have therapeutic value in inflammopathologies in which Plasminute plays a role.

In its capacity as a serine protease, plasmin plays a role in normal processes involving cell migration in tissue remodeling. In this regard, plasmin is believed to function in processes in which cell movement is essential, such as macrophage invasion in inflammation and angiogenesis. Involvement of plasmin in these processes is supported by the ability of plasmin to degrade extracellular matrix proteins directly, such as proteoglycans, fibronectin, laminin, and type IV collagen, and/or be indirectly responsible for the degradation of matrix proteins through activation of metalloprotease zymogens, such as stromolysin and procollagenase. As a result of degradation of the extracellular matrix, cell migration into surrounding areas becomes more facile (Castellino, FJ in *Molecular Basis of Thrombosis and Hemostasis*, High, KA & Roberts, HR, editors, New York, pp 495-515 (1995) which disclosure is hereby incorporated by reference in its entirety).

Neovascularization plays a role in a number of diseases, including but not limited to rheumatoid arthritis (Danis, RP et al., Expert Opin. Pharmacother. 2:395-407 (2001) which disclosure is hereby incorporated by reference in its entirety).

In a further preferred embodiment, the present invention provides for a method of contacting and specifically binding to Plasminute said antibody having the capacity to neutralize the serine protease activity of Plasminute or to facilitate the elimination of Plasminute from tissue. Further preferred is a method of using said antibody in contact with Plasminute as a therapeutic for patients with inflammopathology. Preferred compositions comprise said Plasminute antibody or fragments or derivatives thereof. Preferred formulation of said composition is that compatible with the route of delivery wherein said route of delivery is selected from, but not restricted to the group consisting of: (a) Oral; (b) Transdermal; (c) Injection; (d) Buccal; and (e) Aerosol.

In further preferred embodiment, the present invention provides for a method of contacting and specifically binding to Plasminute said antibody having the capacity to neutralize the serine protease activity of Plasminute or to facilitate the elimination of Plasminute from tissue. Further preferred is a method of using said Plasminute antibody to treat patients with inflammopathology. Further preferred is a method of using said composition comprised of said Plasminute antibody to ameliorate the symptoms or pathology associated with said inflammopathology. Said Plasminute antibody ameliorates the symptoms or pathology associated with said inflammopathology by blocking the proteolytic remodeling of matrix that is directly or indirectly mediated by Plasminute and that facilitates the inflammatory process, including macrophage invasion, or angiogenesis that is associated with the pathology. Further preferred is a method of delivering to patients with said

- inflammopathology an ameliorative effective amount of said Plasminute antibody wherein said inflammopathology is selected from, but not restricted to, the group consisting of: (a) Rheumatoid arthritis; (b) Atherosclerosis; (c) Inflammatory bowel disease; (d) Insulin dependent diabetes mellitus (Type 1 diabetes); (e) Systemic lupus erythematosus; (f) Multiple sclerosis; (g) Psoriasis;
- 5 (h) Allergic asthma; (i) Septic shock; and (j) Reperfusion injury.

- Proliferative diabetic retinopathy (PDR) remains one of the major causes of acquired blindness in developed nations. The hallmark of PDR is neovascularization, abnormal angiogenesis that may ultimately cause severe vitreous cavity bleeding and/or retinal detachment. In a further embodiment of the invention, said composition comprised of neutralizing anti-
- 10 Plasminute antibody is used in a method to treat patients with said PDR.

- In its capacity as a serine protease, plasmin plays a role in pathological processes of cell migration that are involved in tumor cell growth and invasion of surrounding tissue and, perhaps, metastases [Andreasen, PA et al., *Cell. Mol. Life Sci.* 57:25-40 (2000), which disclosure is hereby incorporated by reference in its entirety]. Involvement of plasmin in these processes is supported
- 15 by the ability of plasmin to degrade extracellular matrix proteins directly, such as proteoglycans, fibronectin, laminin, and type IV collagen, and/or be indirectly responsible for the degradation of matrix proteins through activation of metalloprotease zymogens, such as stromolysin and procollagenase. As a result of degradation of the extracellular matrix, cell migration into surrounding areas becomes more facile (Castellino, FJ in *Molecular Basis of Thrombosis and*
- 20 *Hemostasis*, High, KA & Roberts, HR, editors, New York, pp 495-515 (1995) which disclosure is hereby incorporated by reference in its entirety).

- The urokinase plasminogen activator system, and by implication plasmin, is associated with high risk of tumor invasiveness and metastases [Konno, H et al., *Jpn. J. Cancer Res.* 92:516-23 (2001); Fisher, JL et al., *Clin. Cancer Res.* 7:1654-60 (2001); Vazquez-Rivera, F et al.,
- 25 Proceedings of the 11th NCI-EORTC-AACR Symposium, Abstract 294 (2000); Ellrieder, V et al., *Annals of Oncology* 10, suppl.4, 41-45 (1999); Smolarz, B et al., *Med. Sci. Monit.* 5:833-7 (1999); Romer, J et al., *J. Invest. Dermatol.* 116:353-8 (2001); Abe, J et al., *Cancer* 86:2602-11 (1999); Morii, T et al., *Anticancer Res.* 20(5A):3031-6 (2000); Tecimer, C et al., *Gynecol. Oncol.* 80:48-55 (2001); Zheng, Q et al., *J. Cancer Res. Clin. Oncol.* 126:641-6 (2000); Swiercz, R et al. *Oncol.*
- 30 *Rep.* 8:463-70 (2001); Borgfeldt, C et al. *Int. J. Cancer* 92:497-502 (2001); He, C et al., *J. Cancer Res. Clin. Oncol.* 127:180-6 (2001); which disclosures are hereby incorporated by reference in their entirety].

- In further preferred embodiment, the present invention provides for a method of contacting and specifically binding to Plasminute said antibody having the capacity to neutralize the serine
- 35 protease activity of Plasminute or to facilitate the elimination of Plasminute from tissue. Further preferred is a method of using said Plasminute antibody to treat patients with cancer. Further preferred is a method of using said composition comprised of said Plasminute antibody to

ameliorate the symptoms or pathology associated with said cancer. Said Plasminute antibody ameliorates the symptoms or pathology associated with said cancer by blocking the proteolytic remodeling of matrix that is directly or indirectly mediated by Plasminute and that facilitates the invasive and metastatic processes or angiogenesis that is associated with the pathology. Further preferred is a method of delivering said composition comprised of said Plasminute antibody by intravenous injection. Further preferred is a method of delivering to patients with said cancer an ameliorative effective amount of said Plasminute antibody wherein said cancer is selected from, but not restricted to, the group consisting of: (a) Melanoma; (b) Squamous cell carcinoma of the skin; (c) Breast carcinoma; (d) Lung small-cell carcinoma; (e) Colon carcinoma; (f) Hodgkin's lymphoma; (g) Non-Hodgkin's lymphoma; (h) Prostatic carcinoma; (i) Pancreatic carcinoma; (j) Osteosarcoma; (k) Uterine carcinoma; (m) Ovarian carcinoma; (n) Chondrosarcoma; (o) Endometrial cancer; (p) Testicular carcinoma; (q) Renal carcinoma; (r) Hepatic carcinoma; (s) Lung non-small-cell carcinoma; (t) T lymphocyte acute lymphoblastic leukemia (T-ALL); (u) B lymphocyte acute lymphoblastic leukemia (B-ALL); (v) Acute myeloid leukemia (AML); (w) Chronic lymphocytic leukemia (CLL); and (x) Multiple myeloma.

In a further preferred embodiment, the present invention provides for a method of screening test compounds for the ability to bind Plasminute and specifically neutralize the serine protease activity of Plasminute. Further preferred are said test compounds that bind to either a non-conformational or conformational site on Plasminute. Further preferred are test compounds that neutralize said serine protease activity of Plasminute either sterically or allosterically. Further preferred is a method of screening said test compounds for the capacity to neutralize said serine protease activity of Plasminute. Methods of screening said test compounds for the capacity to neutralize said serine protease activity of Plasminute are well known to those skilled in the art and include, but are not limited to: contacting the test compound with Plasminute, incubating the test compound-Plasminute complex with a substrate of Plasminute, and following proteolytic activation of the Plasminute substrate.

Preferred formulations of said compound are those selected from, but not restricted to, the group consisting of: (a) Oral; (b) Transdermal; (c) Injection; (d) Buccal; and (e) Aerosol.

Said compounds found to bind to and specifically neutralize the serine protease activity of Plasminute are used in methods analogous to those described above for neutralizing anti-Plasminute antibody.

**Protein of SEQ ID NO:56 (internal designation Clone 519757\_184-4-2-0-F7-F)**

The cDNA of clone 519757\_184-4-2-0-F7-F (SEQ ID NO:55) encodes the human intracellular signaling protein comprising the amino acid sequence:

MLEVSDALGGPGRVPGATAGMNGVDTSLLCDLLQALTFLTRNEILCIHDTFLKLCPPGKY  
YKEATLTMDQVSSLPALRVNPFDRICRVFSHKGMFSFEDVLGMASVFSEQACPSLKIEYA  
FRIYDFNENGFIDEEDLQRIILRLLSDDMSDLLMDLTNHVLSDDLNDNMLSFSEFEHA

MAKSPDFMNSFRIHFWGC and shares features with the Calcium and Integrin-Binding (CIB)- and the DNA-dependent kinase interacting (KIP) protein. It will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:55 and polypeptides of SEQ ID NO:56, described throughout the present application also pertain to the human cDNA of clone 5 519757\_184-4-2-0-F7-F and polypeptide fragments encoded thereby. Polypeptide fragments having a biological activity described herein and polynucleotides encoding the same are included in the present invention. Related polypeptide sequences included in the present invention are MGQCLRYQMH

WEDLEEYQALTFLTRNEILCIHDTFLKLCPPGKYYKEATLTMDQVSSLPALRVNPFDRDI

NSDDMSEDLLMDLTNHVLSESDLDNDNMLSFSEFEHAMAKSPDFMYSFRIRFWGC.

The gene of SEQ ID:55 is located on chromosome 2, is ubiquitously expressed, has two EF-hand calcium- and zinc-binding domains, regulates  $Ca^{2+}$ -dependent dephosphorylation processes such as neuronal transmission, muscle glycogen metabolism, and lymphocyte activation and is hereby referred to as CALSIGN. CALSIGN stimulates signaling processes which lead to platelet aggregation and blood clot formation. It binds to the cytoplasmic domain of integrins and regulates integrin function in physiological processes via the fibrinogen receptor (integrin  $\alpha_{IIb}\beta_3$ ), which is expressed on platelets, and thereby activates integrin for binding to fibrinogen, fibronectin, the von-Willebrand factor, vitronectin, and thrombospondin; it also binds to the

15

20 interferon 1-receptor and contributes to signal transduction events in platelets, which lead to strong cell-cell adhesion, platelet aggregation, and blood clot formation. CALSIGN also facilitates immune responses via restoration of surface antigen expression and T-cell activation in response to viral- and bacterial infections and to endogenous factors. Further characteristics of CALSIGN comprise VDJ-recombination in B-cell maturation and surface antigen expression on mature B-

25

cells [Naik et al., J.Biol.Chem.272:4651-4654, 1997; PCT WO 98/14471, 1998; Wu and Lieber, Mutat.Res.385:13-20, 1997; PCT WO 98/31796, 1998; Hynes, Cell 69:11-25, 1992; Smyth et al., Blood 81:2827-2843, 1993; US Patent 6,093,565, 2000, which references are hereby incorporated in their entirety].

In a preferred embodiment, CALSIGN or other polypeptides of the invention are used in a

30

method for tissue regeneration and wound healing after injuries. Wounds, in particular those occurring in the skin as second and third degree burns, stasis ulcers, trophic lesions such as decubitus ulcers, severe cuts and abrasions, which are commonly resistant to natural healing processes, may be treated with a composition comprising CALSIGN or other polypeptides included in the invention, or fragments thereof, in a formulation, which might include a growth

35

factor such as platelet derived growth factor (PDGF) or connective tissue growth factor (CTGF), or a wound dressing with aseptic properties such as silver-coated fibers (US Patent 6,149,916, 2000; US patent 6,187,743, 2001; US Patent 6,087,549, 2000), which references are hereby

incorporated in their entirety.

The process of wound healing consists of three phases during which the injured tissue is repaired, regenerated, and new tissue is reorganized into a scar. These three phases are classified as: a) an inflammation phase which begins from day 0 to 3 days, b) a cellular proliferation phase from 3 to 12 days, and c) a remodeling phase from 3 days to about 6 months. In all three phases, antioxidants play a vital role in the healing process. In the inflammation phase, inflammatory cells, mostly neutrophils, enter the site of the wound followed by lymphocytes, monocytes, and later macrophages. The neutrophils that are stimulated begin to release proteases and reactive oxygen species into the surrounding medium with potential adverse effects on both the adjacent tissues and the invading microorganisms. The oxygen species known to be released by the neutrophils are superoxide ( $O_2^{\cdot-}$ ) through the action of a plasma membrane-bound NADPH oxidase, hydrogen peroxide ( $H_2O_2$ ) formed by action of dismutation of  $O_2^{\cdot-}$ , and HOCl produced by the action of myeloperoxidase with  $H_2O_2$ .

The proliferative phase consists of laying down new granulation tissue, and the formation of new blood vessels in the injured area. The fibroblasts, endothelial cells, and epithelial cells migrate in the wound site. These fibroblasts produce the collagen that is necessary for wound repair. Ascorbic acid is crucial in the formation of collagen. Several studies have demonstrated that ascorbic acid was capable of overcoming the reduced proliferative capacity of elderly dermal fibroblasts, as well as increasing collagen synthesis in elderly cells by similar degrees as in newborn cells even though the basal levels of collagen synthesis are age dependent. A decrease of ascorbic acid at the injury area will decrease the rate of wound healing. In reepithelialization, epithelial cells migrate from the free edges of the tissue across the wound. This event is succeeded by the proliferation of epithelial cells at the periphery of the wound. Research has also shown that reepithelialization is enhanced by the presence of occlusive wound dressings which maintain a moisture barrier. The final phase of wound healing, which is remodeling, is effected by both the replacement of granulation tissue with collagen and elastin fibers and the devascularization of the granulation tissue. Recent studies have shown that topical application of antioxidants, especially alpha-tocopherol, reduces scarring and normalizes blood coagulation during therapy.

A particularly effective healing treatment for wounds and skin defects such as burns, ulcers and lesions is the application of a medicinal dressing containing as an essential ingredient starch hydrolysate having Dextrose Equivalent of less than about 35. In such wound treatment the starch hydrolysate produces the formation of a film which is intimately adhered to the underlying granulation tissue and which is semi-permeable to gas and fluids and provides an ideal protective cover that will reduce fluid and plasma losses and invasion by pathogenic bacteria. In addition, it appears that the starch hydrolysate provides a topical or local hyperalimentation, that is local nutrition, providing a gradual release of glucose which is particularly effective in nutrition of tissue, both damaged and nascent, which have become relatively isolated from normal blood flow

nutrition. The cessation of blood flow to such an ischemic lesion can be developed in a slow and gradual form such as in the case of decubitus ulcers and stasis ulcers, or may take place more acutely such as in thermo-radiation and chemical burns. In the absence of nutrition, the rate of fluid delivery of nutrients decreases bringing a progressive impairment in the viability of cells and tissues. This eventually leads to degeneration and death of the tissue and cells in a condition known as necrosis. Necrosis is generally accompanied by bacterial, fungal and/or viral contamination. As further pointed out in the aforementioned patent, treatment of exudative skin wounds with a starch hydrolysate dressing produces a greatly reduced bacteria count of an infected wound and inhibits infection of an uninfected wound. In addition, application of the starch hydrolysate to a wound or ulcer produces a film or semi-permeable membrane which allows edematous liquid to pass through while proteinaceous material is retained within the body, allowing reduction in the volume of exudate in relatively clean condition.

Compositions which enhance and promote the wound healing process comprise suspensions of CALSIGN, said fibrous protein, collagen, and a polysaccharide such as a glycosaminoglycan, which exhibits chemotaxis for fibroblasts or endothelial cells; the preferred glycosaminoglycans are said to be heparin, heparan sulfate, or alginate; collagen type I, vitamins such as ascorbic acid (vitamin C) and alpha-tocopherol (vitamin E), and particulate starch hydrolysate are applied on wounds to promote the formation and growth of healthy granulation tissue. Wound healing processes will be significantly improved by multilayer laminate "wound dressings" comprising alternate layers of silver or silver-coated fibers and non-metalized fibers, which promote cellular proliferation and comprise antibacterial, antifungal, and analgesic properties (US Patent 6,087,549, 2000). The repair process for even minor breaches or ruptures takes a period of time extending from hours and days to weeks; and in some instances, as in ulceration, the breach or rupture may persist for extended periods of time, i.e., months or even years. At all times, be it brief or extended, the potential for invasion by pathogenic organisms or foreign substances continues until new tissue has been generated to fully close the rupture or breach. Because of the danger of infections, the customary management of wounds includes an initial thorough cleansing of the affected area to remove any contaminants such as dirt, cloth particles, or other debris that may introduce pathogenic materials. Any hopelessly damaged tissues may be debrided and antiseptic materials are applied to make the area as sterile as possible. If considered necessary, sutures may be used to reduce the area of the underlying tissues and thereby limit the amount of tissue exposed to subsequent contamination. The healing process is brought about by complex biological mechanisms generally involving several groups of special cells and proteins. Leukocytes, such as neutrophils and macrophages, crown the wound site and digest foreign pathogens and debris. Such cells also send out chemical signals that marshal fibroblasts in the wound vicinity and ultimately generate connective structures, principally, collagen, which make up a major portion of the new tissues. Endothelial cells generate new blood capillaries that

grow into the reconstructed tissue areas where their presence is necessary to supply nutrients to the newly growing tissue cells and remove catabolic products. As the new capillaries grow, the cells on the margin of the wound simultaneously multiply and grow inwardly. The fibrous tissue arising from this cell growth eventually fills the wound cavity with a network of interlacing threads of collagen which in due time, arrange themselves in firm bands and form the permanent new tissue.

Said method for promoting wound healing comprises the steps of:

Applying to the wound a composition of a therapeutically effective concentration of CALSIGN or other polypeptides included in the invention in an aqueous suspension with bovine collagen type I and alpha-tocopherol in a mixture with starch hydrolysate of a low dextrose equivalent DE, wherein said composition is chemotactic for fibroblasts and endothelial cells. Said bovine collagen is pre-treated to remove extraneous proteinaceous material by various dissolution, precipitation and filtration techniques to provide pure collagenous product.

The composition may be combined with a combination of vitamins such as vitamin C and vitamin E, and with a therapeutically effective concentration of a purified connective tissue growth factor (CTGF), and platelet derived growth factor (PDGF).

Said aqueous suspension is applied repeatedly to the wound during the healing to effectively promote the healing process

Said aqueous suspension may be combined with said multilaminate silver dressing for the treatment of postoperative wounds

These embodiments also include the production of an antibody against CALSIGN and other polypeptides of the invention, wherein said antibodies can be polyclonal or monoclonal. For the production of recombinant CALSIGN, an expression vector and a corresponding cell system will be used, wherein the expression system can be prokaryotic such as E.coli, and eukaryotic such as Baculovirus/insect cells, or mammalian systems as well-known in the art.

#### **25 Protein of SEQ ID NO:58 (internal designation Clone 625004\_188-15-4-0-H6-F)**

The cDNA of clone (SEQ ID NO:57) encodes the protein of SEQ ID NO:58, comprising the sequence:

MGPPGFKGKTGHPGLPGPKGDCGKPGPPGSTGRPGAEGEPGAMGPQGRPGPPGHVGP  
PGQPGPAGISAVGLKGDRGATGERGLAGLPQPGPPGPGYGKMATGMGQQGIPGI  
PGPPGPMGQPGKAGHCNPSDCFGAMPMEQQYPPMKTMKGPF.

Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:58 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in clone 625004\_188-15-4-0-H6-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:57 described throughout the present application also pertain to the nucleic acids included in clone 625004\_188-15-4-0-H6-F. Also preferred are fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The cDNA of SEQ ID NO:57 is a novel splice variant of the human alpha 1 type XVI collagen gene (GB M92642.1) located on chromosome 1, specifically in the p34-35 region. The cDNA clone of SEQ ID NO:57 encodes an open reading frame of 489 nucleotides. Whereas the native form of human alpha 1 type XVI collagen possess 71 exons encoding a 1603 amino-acid protein, the cDNA of SEQ ID NO:57 contains 14 exons and encodes a 163 amino-acid protein of SEQ ID NO:58. The present protein represents the first described variant of the human alpha 1 type XVI collagen, named vCOL16A1. The present protein contains two collagen triple helix repeat domains (positions 11-70 and 73-131).

Collagens represent a large family of structurally related proteins that to date includes more than 20 collagen types. These proteins constitute the major extracellular matrix components of connective tissues and play a dominant role in maintaining the structural integrity of various tissues and also have a number of other important functions. Collagens can be divided into two major classes: the fibril-forming collagens and the non-fibril-forming collagens; the latter class includes a subgroup named the fibril-associated collagens with interrupted triple helices (FACIT). The human alpha 1 type XVI collagen exhibits most of the characteristics of the proteins of the non-fibril-forming collagen class.

In one embodiment, the protein of the invention or fragment thereof provide an *in vitro* assay to test the specific activity of various proteases which degrade or denature collagen, such as collagenases and many others. Methods to assess the activity of such proteases include the steps of contacting the protease to be tested with the present protein, and detecting the amount of proteolytic cleavage of the present protein that occurs.

Since collagen fibrils are often heterogenous structures containing more than one collagen type, the present invention provides a method to determine the types of collagen present in a tissue or biological sample. For example, the collagen composition of a diseased tissue can be determined by isolating the present protein under conditions that do not disrupt protein-protein interactions, and determining the identity of proteins associated with the present protein. Such associated proteins can be identified by any standard method including, but not limited to, immunoprecipitation and immuno-affinity columns.

The present invention also provides animal models generated by modulating the expression or activity of the present protein in one or more tissues of the animal. Such animals are useful for a number of purposes, for example because they represent an *in vivo* assay method for testing candidate molecules potentially useful for the treatment of various pathophysiological aspects of diseases associated with abnormal collagen metabolism specifically related to the activity of the present protein. Study of the phenotype of such models can also allow the identification of additional human equivalent diseases caused by or linked with collagen mutations. These animals can be generated with any method of targeting overexpression or inactivation of the present protein. In one such embodiment, purified forms of the present protein are injected into the joints

of an animal, or the protein is recombinantly expressed in the joints, to provoke "collagen induced arthritis" in the joints, a well known model for arthritis. Such models are extremely useful, e.g. in the assessment of candidate therapies and drugs for the treatment of arthritis and other inflammatory diseases and conditions.

5 In other embodiment, the protein of the invention or fragment thereof is used to diagnose diseases or disorders associated with abnormalities of the metabolism of collagen. Examples of such diseases and disorders include, but are not limited to, hereditary nephritis of Alport's type due to a defect in collagen assembly that lead to progressive renal failure, disorders of bone tissue comprising osteoporosis, Paget's disease, disorders of cartilage tissue occurring in arthritis (such as  
10 osteo-arthritis and rheumatoid arthritis), disorders of the cardiovascular system prominent in atherosclerosis, hypertension, myocardial infarction and hypertrophy. This method includes the steps of contacting a biological sample obtained from an individual suspected of suffering from the disease or condition, or at risk of developing the disease or condition, with a compound capable of selectively binding the present protein or nucleic acids, e.g. a polyclonal or monoclonal antibody or  
15 any immunologically active fragment thereof, a nucleic acid probe, etc., and detecting the level, spatial distribution, or any other detectable property of the present protein in the sample, where a difference in the level, spatial distribution, or other property in the sample relative to in a control sample indicates the presence of the disease or disorder, or of a propensity for developing the disease or disorder.

20 A further embodiment of the present invention is to provide novel methods and compositions useful for the treatment of diseases and conditions associated with collagen matrix destruction, including for wound treatment, including fractures. Such methods comprise the administration of a therapeutically-effective amount of the present protein to a patient suffering from the disease or condition. Preferably, the protein is administered directly to the site of  
25 collagen matrix destruction. The methods and compositions can also be used in, for example, the restoration of surgically induced wounds, or for the correction of physiological malfunction, for example to control urinary incontinence and more specifically for intrinsic sphincter deficiency. In such methods, the present protein can be administered by peri-urethral injection to reduce lumen aperture. These compositions can comprise the protein of the invention, and, optionally, one or  
30 more other types of collagen, collagen derivatives, or any other compound of interest. All of these components may be either obtained from natural sources or produced by recombinant genetic engineering techniques and/or chemical modification.

Since aberrant degradation of collagen is an indication of disorders of connective tissues, another embodiment the present invention is to provide an assay for the monitoring of collagen  
35 degradation *in vivo*. The invention thus includes test kits useful for the quantification in a biological sample of the amount of collagen fragment derived from the degradation of collagen, i.e. the degradation of the present protein. The kits comprise at least one immunological binding

partner, e.g. a monoclonal or polyclonal antibody specific for a peptide derived from the degradation of the present protein or the intact present protein and coupled to detectable markers. Collagen degradation can be measured effectively in plasma, serum or blood by any suitable method, including immunoassays. Thus, the condition of a subject can be monitored continuously

- 5 and the quantified amount of collagen fragments measured in the pathological sample can be compared with the amount quantified in a biological sample of a normal individual.

In this embodiment, the application of such assays can be used to monitor the progress of therapy administered to treat these or other conditions. Further, the assays can be used as a measure of toxicity, since the administration of toxic substances often results in tissue degradation.

- 10 It can also be used during clinical testing of new drugs to assess the impact of these drugs on collagen metabolism. Thus the assays may be applied in any situation wherein the metabolic condition of collagen tissues can be used as an index of the condition, treatment, or effect of substances directly administered to the subject or to which the subject is exposed in the environment.

- 15 Also in this embodiment, the present invention provides a method of detecting the presence and/or monitoring the metastatic progress of a malignancy. Indeed, metastatic potential can be influenced both positively and negatively by a variety of cell surface adhesive molecules that act both independently and in concert with connective tissue elements such as collagen, allowing subsequent growth of tumor cells at secondary sites in particular tissues. The invention
- 20 thus includes test kits useful for quantify the amount of the present protein or any specifically associated collagen type in a biological sample comprising the steps of contacting the biological sample with a specific monoclonal or polyclonal antibody specific for the present protein or any specifically associated collagen type, and coupled to detectable markers. Thus, the condition of a patient can be monitored continuously and the quantified amount of such proteins measured in the
- 25 pathological sample can be compared with the amount quantified in a biological sample of a normal individual or with the previous analysis of the same patient.

- Excessive production and deposition of collagen leads to fibrosis and thereby impairs the normal functioning of the affected organ and tissues. There are numerous examples of fibrosis, including the formation of scar tissue following a heart attack, which impairs the ability of the
- 30 heart to pump. Diabetes frequently causes damage/scarring in the kidneys which leads to a progressive loss of kidney function. Even after surgery, scar tissue can form between internal organs causing contracture, pain, and in some cases, infertility. Thus, the present invention provides a method to inhibit collagen accumulation, specifically the accumulation of the present protein, and thereby to avoid delayed healing. The level of the present protein can be inhibited or
- 35 decreased using any of a number of methods, including using antisense molecules or ribozymes, or alternatively the activity of the present protein can be inhibited using direct or indirect inhibitor molecules or antagonistic antibodies directed against the present protein. The inhibition of the

expression or the activity of the present protein is also useful in the treatment of acute fibrosis (in response to various forms of trauma including injuries, infections, surgery, burns, radiation, chemotherapy treatments) or in the treatment of chronic fibrosis of the most commonly affected organs (heart, liver, kidney, lung, eye and skin), e.g. induced by viral infection, diabetes,

5 hypertension or other chronic conditions.

In another embodiment, the invention is useful for preparing cosmetic compositions such as skin creams with anti-wrinkle activity. Cosmetic applications also include the use of the present invention as a dermal implant to increase tissue size by injections of collagenous suspensions following eyebrow uplift, for lip augmentation and to rectify facial defects, frown lines and acne  
10 scars. The present protein can be used as an injectible biomaterial as a dermal implant to increase tissue size for cosmetic (wrinkle reduction). The protein of the invention is held to be an ideal biomaterial due to its ability to persist in the body long enough to carry out its specific role without developing a foreign body response that could lead to the premature rejection or overall failure of the biomaterial. These compositions can comprise purified forms of the present protein and,  
15 optionally, one or more other types of collagen or collagen derivatives. All of these components may be either obtained from natural sources or produced by recombinant genetic engineering techniques and/or chemical modification.

The present invention can also be used in a variety of applications as a food source. Since the transmission risks of bovine spongiform encephalopathy to humans from various commonly  
20 used bovine derived products, such as bovine collagen, are still unclear, there is a need for alternative products to replace bovine derived products. Thus, another advantage of the present invention is derived from the fact that it is a human collagen rather than an animal-derived collagen. It is useful for making a casing for food products that are usually sausages, but the present invention can also be applied to any type of material including animal meat, fish meat,  
25 shellfish, and fish eggs, such as salmon roe, cheese, noodles. In addition, the present protein can be used as the binder element instead of caseins, which have been considered in the art to be indispensable for obtaining satisfactory binding strength in bound food. Thus, consumers who are allergic to these proteins can enjoy the bound food prepared containing the present invention without the fear of having an allergic reaction. The use of the present invention is also attractive  
30 for pet food, for example dogs or cats, and can be even more so if it is combined with solid products conventionally used in animal nutrition, for example pieces of meat or fish, and/or extruded cereals and/or extruded proteins. In a such embodiment, the present invention can be deliverable as a mixture, including, but not limited to, in a fluidized state, as a mixture in a gel state, in a freeze-dried state, or in a salt-precipitated state.

35 In another embodiment, the present protein can be used as a biomaterial for tissue engineering, to regenerate or replace damaged tissues. The present invention thus provides various clinical applications for the generation of tissues or organs unable to repair or regenerate

themselves. It can be used, for example, to promote bone regeneration, to repair tendons, ligaments or cartilage, to generate blood vessels or heart valves, to create dental implants, but also in burn injuries, for dermal replacement in chronically unstable scars, after skin loss for hereditary, traumatic or oncological reasons, or for corneal reconstruction (see, e.g. Atala, (2000) J Endourol Feb;14(1):49-57; Schwartzmann (2000) Implant Dent 9(1):63-6; Machens et al.(2000) Cells Tissues Organs 167(2-3):88-94; the disclosures of which are hereby incorporated by reference in their entireties). The present invention is suited to the culturing of three-dimensional mammalian tissues for purposes including transplantation or implantation in vivo, and as the primary component of an extracorporeal organ assist device. Methods are also provided involving stem cells, for example pluripotential cells, which can differentiate into various tissue types (muscle, cartilage, skin, bone, etc) when stimulated by an appropriate environment, e.g. comprising the present protein. For example, stem cells can be expanded in vitro and suspended in collagen gel matrices to form composites. The resulting composites will be implanted in a gap defect as a graft, which after remodeling in vivo, becomes populated with host cells and recapitulates normal functional architecture. In this embodiment, these substitutes can also serve as in vitro models for toxicology testing to better understand the response and healing mechanisms in human tissues.

**Protein of SEQ ID NO:60 (internal designation Clone 422353\_145-11-3-0-E7-F)**

The cDNA of SEQ ID NO:59 encodes the protein of SEQ ID NO:60, comprising the sequence:  
 MCFPKVLSDDMKKLKARMHQAIERFYDKMQNAESGRGQVMSSLALEDDFKEGYLET  
 V  
 AAYYEEQHPELTPLEKERDGLRCRGNRSPVPDVEDPATEEPGESFCDKVMRWFQAMLQ  
 RLQTTWWHGVLAWVKEKVVALVHAVQALWKQFQSFCCSLSELMSSSFQSYGAPRGDKEE  
 LTPQKCSEPQSSK. Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:60 described throughout the present application also pertain to the polypeptide encoded by the nucleic acids included in clone 422353\_145-11-3-0-E7-F. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:59 described throughout the present application also pertain to the nucleic acids included in clone 422353\_145-11-3-0-E7-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:59, SEQ ID NO:60, and Clone 422353\_145-11-3-0-E7-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:60 (NK5) is a novel splice variant of the human Natural Killer cells protein 4 precursor (NK4) (Genbank accession number M59807). NK5 is a 188-amino-acid-long protein that displays an RGD cell-attachment sequence from positions 170 to 172. An epitope, located from positions 163 to 187, overlaps this RGD motif. NK5 displays a putative trans-membrane domain from positions 148 to 168. Contrarily In contrast to NK4, NK5 displays no signal peptide. The NK4 cDNA contains 6 exons (Bernot *et al.*, Genomics 50:147-60 (1998)), whereas the NK5 cDNA contains 7 exons. Exons 1 and 2 are identical for NK4 and NK5, and

exons 5, 6 and 7 of NK5 are identical to exons 4, 5 and 6 of NK4. Exon 3 of NK5 is shorter than exon 3 of NK4, and exon 4 is unique for NK5.

NK4 gene expression is ubiquitous (Bernot *et al.*, Genomics 50:147-60 (1998)).

Nevertheless, its expression is greatly increased in mitogen-activated T cells and in IL-2-activated

5 Natural Killer cells (Dahl *et al.*, J. Immun. 148:597-603 (1992)).

Natural killer (NK) cells and T cells provide anti-infectious, anti-neoplastic, and immunomodulatory function effected by both cytokine production and direct cellular cytotoxicity. In particular, NK cells play a primary role in preventing and removing cancer cells in the body, removing many types of viruses (including herpes and measles) and have been found to be present

10 at low levels in women with endometriosis. Moreover, in addition to these overtly immunoprotective functions, NK cells also mediate a variety of homeostatic functions, particularly in the regulation of haematopoiesis and they may have an important role to play in the maintenance and development of placentation. The behaviour of NK and T cells in these various situations is regulated by a large number of distinct receptors that transmit positive and negative signals.

15 Resting NK and T cells express a number of surface molecules which, when stimulated, can activate the cytotoxic mechanism. The balance of these signals determines whether an NK or T cell does nothing or is activated to proliferate, kill or secrete a wide range of cytokines and chemokines. More particularly, IL-2 activates many NK-cell functions, including baseline or "natural" anti-tumor cytotoxicity, antibody-dependent cellular cytotoxicity (ADCC), proliferation, 20 and cytokine production (Trinchieri, Adv. Immunol. 47:187-376 (1989)), and IL-2-activated NK cells display a broader spectrum of reactivity against human and murine tumor target cells.

The RGD motif, which is found in a number of proteins, has been shown to play a role in cell adhesion. It was shown that anchorage of NK cells is necessary for full activation (Li *et al.*, J Immunother 20:123-30 (1997)), and that long term-activated NK cells acquire new adhesive 25 properties. This suggests a central role for RGD recognition in the regulation of immune responses.

The expression of the NK5 gene is greatly increased in IL2-activated NK cells and in mitogen mitogen-activated T cells, and thus likely plays an important role in lymphocyte activation. In particular, NK5 is believed to play a role in the new adhesive properties that are 30 acquired by activated lymphocytes. As NK5 does not display a signal peptide, NK5 likely plays a distinct role from NK4 in this process.

An embodiment of the present invention relates to methods of using NK5 or fragment thereof as a marker to selectively detect and/or quantify activated T cells and/or activated NK cells. Any method of detecting the presence, level, or activity of NK5 can be used in such methods. For 35 example, the protein of the invention or fragment thereof may be used to generate specific antibodies using standard methods, and the antibodies can be used to detect the level of the present protein in a NK cell or a T cell, wherein a detection of a higher level of the present protein in the

cell compared to a control level representative of a resting T cell or NK cell indicates that the cell is activated. Preferably, the antibodies are either directly or indirectly labeled, and bind more specifically to NK5 than to related proteins such as NK4. Alternatively, the nucleic acid of the invention or fragment thereof may be used to synthesize specific probes using any technique  
5 known to those skilled in the art. Such antibodies and/or probes may then be used in assays and diagnostic kits for the detection and/or quantification of activated T cells and/or activated NK cells in, e.g., bodily fluids, in tissue samples and in mammalian cell cultures.

In a preferred embodiment, such methods of detecting the polypeptides or polynucleotides of the invention, e.g. using specific antibodies and/or probes, can be used to measure the effect of a  
10 test compound on T cell and/or NK cell activity in mammalian cell cultures. In another preferred embodiment, such methods can be used to monitor the effects of a treatment aiming to increase or decrease T cell and/or NK cell activity in a patient, or to detect the beginning of a graft rejection reaction in a patient.

Another embodiment of the invention relates to compositions and methods for inhibiting  
15 the expression or activity of NK5 in a patient for the treatment or prevention of diseases and disorders caused as a result of T cell and/or NK cell activation. The inhibition and/or reduction of T cell and/or NK cell activation can be achieved using any suitable method, e.g. through the administration of a therapeutically effective amount of an antibody that specifically recognizes NK5 or fragment thereof to a patient. Preferably, the antibody recognizes the epitope overlapping  
20 the RGD domain. The antibody can be administered alone or in combination with one or more agent known in the art, e.g. other immuno-suppressive agents. Administration of the antibody can be done following any method known in the art, including those described in U.S. Patent 5,817,311, which disclosure is hereby incorporated by reference in its entirety. Other inhibitors of NK5 expression or activity which can be used include, but are not limited to, antisense molecules,  
25 ribozymes, dominant negative forms of NK5, and compounds that decrease the activity or expression of NK5 in a cell. Such compounds can be readily identified, e.g. by screening test agents against T cells or natural killer cells expressing NK5, or capable of expressing NK5, and detecting the ability of the test agents to inhibit natural killer cell or T cell activation, or to diminish the level of NK5 expression. Diseases and disorders caused as a result of T cell and/or  
30 NK cell activation include, but are not limited to, allergy and asthma, and the methods can also be used in treatments for preventing and/or inhibiting on-going immune responses. More particularly, such treatments can be used to prevent, or inhibit, or reduce in severity graft rejection, or induce tolerance to graft transplantation. Such transplantation may by way of example include, but not be limited to, transplantation of cells, bone marrow, tissue, solid-organ, bone, *etc.* Such treatments  
35 can also be used to prevent or reduce in severity graft versus host diseases and autoimmune diseases, which by way of example include but are not limited to rheumatoid arthritis, systemic lupus, multiple sclerosis, insulin-dependent diabetes, hepatitis, rheumatoid arthritis, Graves

disease, *etc.*

Another embodiment of the invention relates to the activation and/or prevention of inactivation of NK and/or T cells, based on compositions and methods containing, e.g., NK5 or fragment thereof, a polynucleotide encoding the protein, or a compound that increases the expression or activity of NK5. Such compounds can be readily identified, e.g. by screening test agents against T cells or natural killer cells expressing NK5, or capable of expressing NK5, and detecting the ability of the test agents to enhance natural killer cell or T cell activation, or to increase the level of NK5 expression. Diseases and disorders that may be treated and/or reduced in severity by T cell and/or NK cell activation include but are not limited to tumors, viral infections, inflammation, or conditions associated with impaired immunity, bacterial infections, hepatic dysfunction, liver regeneration, haematopoiesis and maintenance and development of placentation. More particularly, such treatments can be used to treat proliferative disorders (including various forms of cancer such as leukemias, lymphomas, sarcomas, melanomas, adenomas, carcinomas of solid tissue, hypoxic tumors, squamous cell carcinomas, genitourinary cancers, hematopoietic cancers, head and neck cancers, and nervous system cancers, benign lesions such as papillomas, atherosclerosis, angiogenesis), viral infections (in particular HBV, HCV, HIV, hepatitis, measles and herpes viruses infections, as well as other viral-induced infections), and other various immune deficiencies. These immune deficiencies may be genetic (e. g. rheumatoid and osteo arthritis and severe combined immunodeficiency (SCID)) or be caused by various bacterial or fungal infections (e.g. infections by mycobacteria, Leishmania spp., malaria spp. and candidiasis). Of course, NK5 may also be useful where a boost to the immune system generally may be desirable, i.e., in radiation therapy or chemotherapy when treating the cancer. NK5 or fragment thereof can be administered alone or in combination with other known agents capable of activating NK and/or T cells, such as methods described in U.S. Patent 6,245,563 and in U.S. Patent 6,197,302, which disclosures are hereby incorporated by reference in their entireties.

**Protein of SEQ ID NO:62 (Internal Designation Clone 500715621\_204-15-3-0-C6-F)**

The cDNA of Clone 500715621\_204-15-3-0-C6-F (SEQ ID NO:61) encodes the 202 amino acid long polypeptide of SEQ ID NO:62 comprising the amino acid sequence :  
 MELWGAYLLLCLFSLLTQVTTEPPTQKPKKIVNAKKDVVNTKMFEELKSRLDTLAQFEVAL  
 LKEQQALQTVCLKGTKVHMKCFLAFTQTKTFHESSEDCISRGGTLSTPQTGSENDALYEY  
 LRQSVGNEAEIWLGLNDMAAEGTWVDMTGARIAYKNWETEITAQPDGGKTENCAVLSG  
 AANGKWFDKRCRDQLPYICQFGIV. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:62 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 500715621\_204-15-3-0-C6-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:61 described throughout the present application also pertain to the nucleic acids included in Clone 500715621\_204-15-3-0-C6-F. A preferred embodiment of the invention is

directed toward the compositions of SEQ ID NO:61, SEQ ID NO:62, and Clone 500715621\_204-15-3-0-C6-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:62 represents a new variant form of the human tetranectin precursor polypeptide (Swissprot entry P05452), harboring an amino acid substitution at position 94 which replaces an alanine residue by a serine residue. The protein of the SEQ ID NO:62 is a 202 amino acid long polypeptide comprising a 21 amino acid signal peptide followed by a 181 amino acid sequence corresponding to a mature polypeptide of the invention, Plasminogen carrier protein (PLCP).

PLCP is a 68 kilodalton homotrimeric plasminogen-binding protein present in plasma. In addition to plasminogen, PLCP binds calcium as well as a number of sulphated polysaccharides including heparin, chondroitin and fucoidan. It also binds Apolipoprotein A and fibrin.

In terms of primary and tertiary structure, the protein is related to the family of Ca(2+)-binding C-type lectins, proteins that bind a wide diversity of compounds, including carbohydrates, lipids and proteins.

The protein is encoded by three exons corresponding to three functional domains. Exon 3 (nt367 to nt771 on SEQ ID NO: 61) encodes the long-form C-type Lectin domain (aa77 to aa198 on SEQ ID NO:62), also termed the carbohydrate recognition domain (CRD), which is involved in Ca(2+) and plasminogen binding. Exon 2 (nt268 to nt366) encodes an alpha-helix domain that governs the trimerization of PLCP oligomers by assembling into a triple helical coiled-coil structural element. Finally, residues encoded by exon1 (nt13 to nt267), but not the CRD, bind heparin, suggesting a specific role for this domain in sulphated carbohydrate ligand binding (Loretsen et al. 2000, Biochem. J. 347, 83-87 which disclosure is hereby incorporated by reference in its entirety).

PLCP binds plasminogen via its CRD through a specific interaction with the fourth kringle domain of plasminogen, and binding has been reported to facilitate the proteolytic activation of plasminogen to plasmin by the tissue-type plasminogen activator. Because plasminogen activation is involved in a variety of extracellular proteolytic events including fibrinolysis, cell migration, angiogenesis, tumor cell invasion, inflammation, wound healing, and tissue remodeling, PLCP is useful in the modulation of these biological processes.

The present protein is isolated from human blood, but is also found to be deposited in the extracellular matrix of various tissues. In particular, PLCP is deposited in the tumor surrounding stroma of breast, colon, and ovarian tumors and is found to co-localise with plasmin/plasminogen at the invasive front of cutaneous melanoma lesions, whereas little or no PLCP is found in the corresponding normal tissues. Plasma PLCP level is reduced in cancer patients, and PLCP is useful as a prognostic marker for the diagnosis of certain types of cancer.

Preferred PLCP polypeptides for uses in the methods described below include the

polypeptides comprising the amino sequence of:

EPPTQKPKKIVNAKKDVVNTKMFEELKSRLDTLAQEVALLEQQALQTVCLKGTKVHMK  
CFLAFTQTKTFHESSEDCISRGGTLSTPQTGSENDALYEYLRQSVGNEAEIWLGLNDMAAE  
GTWVDMTGARIAYKNWETEITAQPDGGKTENCAVLGAANGKWFDKRCRDQLPYICQF

5 GIV;

A polypeptide comprising the amino acid sequence of:

VCLKGTKVHMKCFLAFTQTKTFHESSEDCISRGGTLSTPQTGSENDALYEYLRQSVGNEA  
EIVLGLNDMAAEGTWVDMTGARIAYKNWETEITAQPDGGKTENCAVLGAANGKWFD  
KRCRDQLPYICQFGIV;

10 A polypeptide comprising the amino acid sequence of:

VHMKCFLAFTQTKTFHESSEDCISRGGTLSTPQTGSENDALYEYLRQSVGNEAEIWLGLND  
MAAEGTWVDMTGARIAYKNWETEITAQPDGGKTENCAVLGAANGKWFDKRCRDQLP  
YICQ

In one embodiment, the cDNA of SEQ ID NO:61 bearing a G to T substitution at position  
15 438, which replaces an alanine residue by a serine at position 94 of SEQ ID NO:62, is used for  
DNA genotyping. Indeed genotyping this locus could be of interest in DNA fingerprinting for  
paternity studies or forensic analyses. It could also be used for genetic association studies,  
especially in pathologies relating to coagulation disorders.

In another embodiment, the polynucleotide sequence of the invention is used in  
20 pharmacogenomic applications in order to aid in the choice of the ideal drug (e.g. a coagulation or  
anticoagulation drug), or dosage of a drug, for the treatment of a condition or disease in a patient.  
For example, in one embodiment, the invention provides a method of genotyping the patient to  
determine the identity of the nucleotide encoding the amino acid at position 438 of SEQ ID NO:62,  
and administering to the patient a drug or a dosage of the drug that has been established to be  
25 preferentially efficacious in those with a serine residue at position 438 (e.g. because of preferential  
binding of the drug to the isoform of the protein with a serine at that position). In another  
embodiment, the patient is genotyped for the nucleotide encoding amino acid position 438, and a  
drug is determined to be not desirably administered to the patient, e.g. because side effects are  
known to be associated with the administration of the drug to individuals with a serine at position  
30 438.

In another embodiment, the present protein is used to copurify plasminogen from a  
biological sample, preferably from a liver cell extract. This is achieved using any method, a large  
number of which are known in the art. For example, plasminogen is purified using affinity column  
chromatography with the protein of SEQ ID NO:62 or by coimmunopurification using a  
35 monoclonal or polyclonal antibody that specifically binds the protein of the invention. Purified  
plasminogen is useful for many purposes, including for the preparation of therapeutic fibrinolytic  
compositions.

In a further embodiment, the present protein provides a method to purify a protein harboring one or more kringle domains from a cellular extract, the method comprising using a fragment of the present protein retaining an intact CRD domain, preferably a fragment restricted to the CRD domain itself, to purify the kringle domain-containing protein, e.g. using a method such as affinity chromatography. Preferably, the protein to be purified is selected from the group consisting of plasminogen, angiostatin, thrombin, Hepatocyte Growth Factor, Macrophage Stimulating Protein and apolipoprotein a. The protein to be purified using the present method is derived from any source, e.g. protein expressed in vitro using an invertebrate, yeast or bacterial heterologous expression system.

10 In another embodiment, the present protein provides a method to determine the localization of plasminogen in vivo or ex vivo. In one such method, a tissue section is contacted with a labeled protein of SEQ ID NO:62, and the labeling in the tissue section is detected. Plasminogen can also be detected directly from crude cell or tissue extracts using the protein of the invention. Methods for labeling proteins are well known in the art, any of which is used in the present invention.

15 In another embodiment, the protein of SEQ ID NO:62 is used to determine circulating levels of plasminogen in the blood of an individual, the method comprising obtaining a blood sample from the individual, using the protein of the invention to copurify plasminogen from the blood sample (e.g. by affinity column chromatography), and measuring the level of plasminogen in the sample using methods well known in the art, for example Elisa, western blot or  
20 radioimmunoassay (RIA). Determining plasminogen levels in circulating blood could be of special interest for the monitoring of patients with diseases associated with impaired coagulation or fibrinolysis.

In another embodiment, the present protein is used as a diagnostic or pronostic marker for breast cancer, ovarian cancer, colon or colorectal cancers, the method comprising contacting a  
25 blood sample from a patient, preferably a serum sample, with an antibody directed to the present protein, and determining the level of PLCP in the sample compared to a control level representative of a healthy patient, wherein a lower level of PLCP in the patient sample relative to the control level indicates that the patient has the disease, is at an elevated risk of developing the disease, or has a worse prognosis than a patient with normal levels of the protein. The antibody  
30 used is either monoclonal or polyclonal and is labeled directly or indirectly for quantification of immune complexes by methods well known to those skilled in the art.

In another embodiment, the present protein provides a transgenic animal, preferably a mammal, more preferably a rodent, with impaired fibrinolytic activity due to no or reduced expression of the protein of SEQ ID NO:62. Such transgenic animals provide a powerful model in  
35 which to study pathologies associated with defective fibrinolysis, especially fibrosis and thrombosis. In addition, such animal is used to screen candidate molecules for the ability to inhibit coagulation or fibrosis.

Transgenic animals with reduced or eliminated PLCP expression or activity is obtained using any of a number of ways, including by PLCP gene knock-out, for example in the mouse, using DNA microinjection into fertilized eggs or transfection of embryonic stem cells.

Alternatively, low level expression of the present protein is achieved using antisense methods, e.g.,

- 5 by placing the reverse nucleotide sequence encoding the protein of SEQ ID NO:62 under the control of a strong promoter sequence. Preferably, a regulatable and ubiquitous promoter sequence is used in order to temporally control the expression of the genetic construct once introduced into the animal. Other methods suitable for use in the present methods include the use of ribozymes, antibodies, and dominant negative forms of the present protein.

- 10 In another embodiment, the present protein provides a method to increase fibrinolysis in an individual, the method comprising administering to said individual an amount of the present protein sufficient to increase plasminogen activation. The present protein is administered in any of a number of ways, including by intravenous injection. Such methods is used in order to eliminate clots in the prevention or the treatment of cardiovascular diseases including, but not limited to,
- 15 strokes or pulmonary embolisms.

**Protein of SEQ ID NO:64 (Internal Designation Clone 165843\_116-008-4-0-G4-F)**

The cDNA of Clone 165843\_116-008-4-0-G4-F (SEQ ID NO:63) encodes Novel Calpastatin 1 (NC1) protein of SEQ ID NO:64, comprising the amino acid sequence:

- MTVLEITLAVILTLLGLAILAILLTRWARRKQSEMHSRYSSEQSARLLDYEDGRGSRHAYS
- 20 TQSERSKRDYTPSTNSLALSRSSIALPQGSMSSIKCLQTTEELPSRTAGAMSKFFFCPLILMC
- FALLNC. Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:64 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 165843\_116-008-4-0-G4-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:64 described
- 25 throughout the present application also pertain to the nucleic acids included in Clone 165843\_116-008-4-0-G4-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:63, 64 and Clone 165843\_116-008-4-0-G4-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

- 30 NC1 is a physiological inhibitor of calpains. Calpains, a group of ubiquitous  $\text{Ca}^{2+}$  - activated cytosolic proteases, have been implicated in cytoskeletal remodeling events, cellular adhesion, shape change, and mobility involving site-specific regulatory proteolysis of membrane- and actin-associated cytoskeletal proteins and apoptosis [Beckerle et al., Cell 51:569-577, 1987; Yao et al., Am. J. Physiol. 265(pt. 1):C36-46, 1993; and Shuster et al., J. Cell Biol. 128:837-848,
- 35 1995; Squier et al., J. Cell Physiol., 178(3): 311-319, 1999]. Calpains have also been implicated in the pathophysiology of cerebral and myocardial ischemia, platelet activation, NF- $\kappa$ B activation, Alzheimer's disease, muscular dystrophy, cataract progression and rheumatoid arthritis. There is

considerable interest in inhibitors of calpain, as cellular adhesion, cytoskeletal remodeling events and cell mobility are linked to numerous pathologies (Wang et al., Trends in Pharm. Sci. 15:412-419, 1994; Mehdi, Trends in Biochem. Sci. 16:150-153, 1991). In addition, as the calpain/calpastatin system is involved in membrane fusion events for several cell types, and

- 5 calpain can be detected in human sperm and testes extracts by Western blotting with specific antisera, tCAST may modulate calpain in the calcium-mediated acrosome reaction that is required for fertilization (Li S et al., Biol Reprod, 63(1):172-8, 2000).

- NC1 has a unique N-terminal domain (domain L) and four repetitive protease-inhibitor domains (domains I-IV) (Lee WJ et al., J Biol Chem, 267(12):8437-42, 1992). The protein of SEQ  
10 ID NO:64 has calpastatin domains T and II. The T domain targets cytosolic localization and membrane association, whereas domain I exhibits a nuclear localization function.

- NC1 plays a role in cytoskeletal remodeling events, cellular adhesion, shape change, and mobility by the site-specific regulatory proteolysis of membrane- and actin-associated cytoskeletal proteins. Preferred polypeptides of the invention are polypeptides comprising the amino acids of  
15 SEQ ID NO:64 from positions 1 to 116. Also preferred are fragments of SEQ ID NO:64 having a biological activity as described therein and the polynucleotides encoding the fragments.

- One embodiment of the present invention relates to methods of using the protein of the invention or fragment thereof in assays to detect the presence of calpain in a biological sample, such as in bodily fluids, in tissue samples, or in mammalian cell cultures. As NC1 binds calpain  
20 (Murachi, Biochemistry Int., 18(2):263-294, 1989), the protein of the invention can be used in assays and diagnostic kits to test the presence of calpain using techniques known to those skilled in the art. Preferably, a defined quantity of the protein of the invention or fragment thereof is added to the sample under conditions allowing the formation of a complex between the protein of the invention or fragment thereof and heterologous proteins, and the presence of a complex and/or the  
25 free protein of the invention or fragment thereof is assayed and compared to a control. NC1 is useful as a marker of intracellular calpain activation, and can be used for monitoring the involvement of calpain in pathological situations (De Tullio et al., FEBS letter, 475(1):17-21, 2000). Calpain has been implicated in cytoskeletal protein degradation involved in the pathophysiology of ischemia and disorders like Alzheimer's disease (Wronski et al., J. Neural  
30 transm., 107(2):145-157, 2000) and Parkinson's disease (Mouatt-Prigent et al., J. Comp. Neurol., 419:175-92, 2000), apoptosis in neural cells of rat with spinal cord injury (SCI) (Ray, Brain res., 867(1-2):80-9, 2000), cell fusibility (Kosower et al., Methods Mol Biol., 144:181-94, 2000) and other physiopathologies. Assays detecting any increased or decreased calpain levels in a cell are thus useful in the diagnosis of any of these diseases or conditions. In addition, a recent study  
35 showed that in addition to their proteolytic activities on cytoskeletal proteins and other cellular regulatory proteins, calpain-calpastatin systems can also affect expression levels of genes encoding structural or regulatory proteins (Chen et al., Am. J. Physiol. Cell Physiol, 279:C709-C716, 2000).

Thus, the ability to detect NC1 and calpain levels is also useful for the diagnosis of an even larger number of diseases and conditions.

In another embodiment, the polynucleotides or polypeptides of the invention may be used for the detection of gametes, gametic precursor cells (such as spermatogenic stem cells), or of specific structures within the gametes, using any technique known to those skilled in the art, including those involving the use of specific antibodies and nucleic acid probes. The ability to visualize spermatozoa generally, or the sperm acrosome in particular, has obvious utility for a number of applications, including for the analysis of infertility in patients.

Another embodiment of the present invention relates to a method of inhibiting calpain in a cell, the method comprising administering to the cell an amount of the present protein sufficient to inhibit calpain in the cell. Such methods can be performed in vitro or in vivo. The inhibition of calpain has numerous uses in the treatment or prevention of various diseases and conditions, for example the pathophysiology of cerebral, myocardial, renal ischemia, platelet activation, NF-kB activation, Alzheimer's disease, Parkinson's disease, muscular dystrophy, cataract progression, cancer cachexia and rheumatoid arthritis. Such an increase can be effected in any of a number of ways, including, but not limited to administering purified protein of the invention directly to the cells, transfecting the cells with a polynucleotide encoding the protein, operably linked to a promoter; and administering to a cell a compound that increases the activity or expression of the protein of the invention. In addition, the expression or activation of the protein of the invention can be inhibited in any of a large number of ways, including using antisense oligonucleotides, antibodies, dominant negative forms of the protein, and using heterologous compounds that decrease the expression or activation of the protein. Such compounds can be readily identified, e.g. by screening candidate compounds and detecting the level of expression or activity of the protein using any standard assay. Other calpain inhibitors are also known which can be used in conjunction with the present protein, or which can be used as controls in the identification of additional inhibitors or activators of calpastatin. Such inhibitors include, but are not limited to, cerebrolysin (Wronski et al., J. Neural Transm. Suppl., 59:263-272, 2000), E-64-D (Ray et al., Brain Res., 867(1-2): 80-9, 2000), and the calpain active site inhibitor N-acetyl-leucyl-leucyl-norleucinal (Squier et al., J. Cell Physiol., 178(3): 311-319, 1999).

In still another embodiment, the protein of SEQ ID:64 or fragment thereof can be used to prevent cells from undergoing apoptosis. Specifically, any method of increasing the level or activity of the present protein in cells can be used to prevent the cells from undergoing apoptosis, in vitro or in vivo. For example, a polynucleotide encoding a protein of SEQ ID NO:64, or any fragment or derivative thereof, can be introduced into cells, e.g. in a vector, wherein the protein is expressed in the cells. Alternatively, a protein of SEQ ID NO:64 itself can be administered to cells, preferably in a formulation that leads to the internalization of the protein by the cells. Also, any compound that increases the expression or activation of the proteins within the cells can be

administered. Preventing cells from undergoing apoptosis can be used for any of a large number of purposes, including, but not limited to, to prevent the death of cells being grown in culture, to prevent in a patient the apoptosis associated with any of a number of disorders, or to prevent apoptosis in cells of a patient undergoing a treatment that increases the level of cellular stress, such as chemotherapy. Furthermore, the invention relates to methods and compositions using the protein of the invention or fragment thereof to diagnose, prevent and/or treat disorders characterized by abnormal cell proliferation and/or programmed cell death, including but not limited to cancer, immune deficiency syndromes (including AIDS), type I diabetes, pathogenic infections, cardiovascular and neurological injury, alopecia, aging, degenerative diseases such as Alzheimer's Disease, Parkinson's Disease, Huntington's disease, dystonia, Leber's hereditary optic neuropathy, schizophrenia, and myodegenerative disorders such as "mitochondrial encephalopathy, lactic acidosis, and stroke" (MELAS), and "myoclonic epilepsy ragged red fiber syndrome" (MERRF). For diagnostic purposes, the expression of the protein of the invention can be detected using any method such as Northern blotting, RT-PCR or immunoblotting methods, and compared to the expression in control individuals, wherein an increase or decrease of the level of the present protein compared to the control level indicates the presence of the disease or condition, or of a propensity for the disease or condition. For prevention and/or treatment purposes of disorders in which cell proliferation needs to be reduced and/or apoptosis increased, the expression of protein of the invention may be enhanced using any method, for example administering the purified protein to cells, transfecting the cells with a polynucleotide encoding the protein, or administering to the cells a compound that increases the expression or activity of the protein. For prevention and/or treatment purposes of disorders in which cell proliferation needs to be enhanced and/or apoptosis reduced, inhibition of endogenous expression of the protein of the invention may be achieved using any method, including triple helix and antisense strategies.

In another embodiment, inhibiting the proteins of the invention can be used to induce apoptosis in undesired cells. Such inhibition can be accomplished in any of a number of ways, including, but not limited to, using antibodies, antisense sequences, dominant negative forms of the protein, or small molecule inhibitors of the expression or activity of the proteins. Such induction of apoptosis can be used to eliminate any undesired cells, for example cancer cells, in a patient. Preferably, such inhibitors are targeted specifically to the undesired cells in the patient using standard methods.

In another preferred embodiment, the protein of the invention can be used to modulate and/or characterize fertility, including for the treatment or diagnosis of infertility, and for contraception. As NC1 is involved in the acrosomal reaction which is a required step in fertilization, over- or under-expression or activation of the present protein can be used to disrupt this reaction and thereby inhibit fertility. For example, for contraception, the expression or activation of the protein can be artificially disrupted, for example by increasing the protein level

using polynucleotides encoding the protein, using the protein itself, or using activators of protein expression or activity, or by decreasing the protein level using inhibitors such as antisense oligonucleotides, antibodies, dominant negative forms of the protein, and using heterologous compounds that inhibit protein expression or activity. Similarly, the cause of infertility in many patients can be detected by detecting the level of expression of the present protein, where an abnormal level of activity or expression of the protein indicates that a cause of infertility involves the calpain-dependent acrosomal reaction. Such a diagnosis would also point to methods of treating the infertility, e.g. by increasing or decreasing the expression or activation of the present protein in spermatozoa.

- 10 In another embodiment, the invention relates to methods and compositions using the protein of the invention or fragment thereof as a marker protein to selectively identify tissues, preferably testis, or to distinguish between two or more possible sources of a tissue sample on the basis of the level of the protein of SEQ ID NO:64 in the sample. For example, the protein of SEQ ID NO:64 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding.
- 20 The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from testis or tissues other than testis to determine whether the test sample is from testis. Similar methods can be used to specifically detect cells expressing the protein, as well as to specifically isolate cells expressing the protein or to isolate the protein itself. For example, an antibody against the protein of SEQ ID NO:64 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:64 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the protein is released from the support by contacting the support with agents which cause the protein to dissociate from the antibody.

- Alternatively, the level of the protein of SEQ ID NO:64 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:64 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from testis or tissues other than testis to determine whether the test sample is from testis. For a number of disorders listed above, particularly of inflammatory processes, expression of the genes encoding the polypeptide of SEQ ID NO:64 at significant higher or lower levels may be routinely detected in

certain tissues or cell types (e.g., cancerous and wounded tissues) or bodily fluids (e.g., serum, plasma, synovial fluid, and spinal fluid) or another tissue of cell sample taken from an individual having such a disorder, relative to the standard gene expression level, i.e., the expression level in healthy tissue or bodily fluid from an individual not having the disorder.

- 5 In another embodiment, the invention relates to methods for using the protein of the invention or fragments to identify autoantibodies which indicate inflammatory processes and particularly, rheumatoid arthritis (RA), a systemic disease characterized by chronic polyarthritis and joint destruction, and in which high levels of autoantibodies directed against calpastatin have been identified. Accordingly, the present protein may be used to detect the presence and/or the
- 10 localization of autoantibodies in a cell. In a typical embodiment, the protein of SEQ ID NO:64 is labeled with any detectable moiety including, but are not limited to, a fluorescent label, a radioactive atom, a paramagnetic ion, biotin, a chemiluminescent label or a label which can be detected through a secondary enzymatic or binding step. The invention further provides a method of diagnosing inflammatory processes, e.g. rheumatoid arthritis, and distinguishing such processes
- 15 from other diseases.

**Protein of SEQ ID NO:66 (Internal Designation 335752\_157-15-4-0-B11-F)**

- The cDNA of Clone 335752\_157-15-4-0-B11-F (SEQ ID NO:65) encodes Novel Calpastatin 2 (NC2) protein of SEQ ID NO:66, comprising the amino acid sequence:
- MTVLEITLAVILTLLGLAILLITRWARRKQSEMYISRYSSSEQSARLLDYEDGRGSRHAYS
- 20 TQSERSKRDYTPSTNSLALSRSIALPQGSMSIKCLQTTEPPSRTAGAMMQFTAPIPGAT
- GPIKLSQKTIVQTLGPIVQYPGSGNINISQLTSEDLTGAKGRVTSGPQFPNSHHVPENLHG
- YMNLSLFSFA. Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:66 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 335752\_157-15-4-0-B11-F. In
- 25 addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:66 described throughout the present application also pertain to the nucleic acids included in Clone 335752\_157-15-4-0-B11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:65, 66 and Clone 335752\_157-15-4-0-B11-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides
- 30 encoding the fragments.

- NC2 is a physiological inhibitor of calpains. Calpains, a group of ubiquitous  $\text{Ca}^{2+}$  - activated cytosolic proteases, have been implicated in cytoskeletal remodeling events, cellular adhesion, shape change, and mobility involving site-specific regulatory proteolysis of membrane- and actin-associated cytoskeletal proteins and apoptosis (Beckerle et al., Cell 51:569-577, 1987;
- 35 Yao et al., Am. J. Physiol. 265(pt. 1):C36-46, 1993; and Shuster et al., J. Cell Biol. 128:837-848, 1995; Squier et al., J. Cell Physiol., 178(3): 311-319, 1999). Calpains have also been implicated in the pathophysiology of cerebral and myocardial ischemia, platelet activation, NF-kB activation,

Alzheimer's disease, muscular dystrophy, cataract progression and rheumatoid arthritis. There is considerable interest in inhibitors of calpain, as cellular adhesion, cytoskeletal remodeling events and cell mobility are linked to numerous pathologies (Wang et al., Trends in Pharm. Sci. 15:412-419, 1994; Mehdi, Trends in Biochem. Sci. 16:150-153, 1991). In addition, as the

- 5 calpain/calpastatin system is involved in membrane fusion events for several cell types, and calpain can be detected in human sperm and testes extracts.

NC2 consists of calpastatin domain T and II. The T domain targets cytosolic localization and membrane association, whereas domain I of exhibits a nuclear localization function.

- The protein of SEQ ID NO:66 is a novel member of the calpastatin family and, as such,  
10 plays a role in cytoskeletal remodeling events, cellular adhesion, shape change, and mobility by the site-specific regulatory proteolysis of membrane- and actin-associated cytoskeletal proteins. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:66 from positions 1 to 116. Also preferred are fragments of SEQ ID NO:66 having a biological activity as described therein and the polynucleotides encoding the fragments.

- 15 One embodiment of the present invention relates to methods of using the protein of the invention or fragment thereof in assays to detect the presence of calpain in a biological sample, such as in bodily fluids, in tissue samples, or in mammalian cell cultures. As NC2 binds calpain, the protein of the invention can be used in assays and diagnostic kits to test the presence of calpain using techniques known to those skilled in the art. Preferably, a defined quantity of the protein of  
20 the invention or fragment thereof is added to the sample under conditions allowing the formation of a complex between the protein of the invention or fragment thereof and heterologous proteins, and the presence of a complex and/or the free protein of the invention or fragment thereof is assayed and compared to a control. NC2 is useful as a marker of intracellular calpain activation, and can be used for monitoring the involvement of calpain in pathological situations (De Tullio et  
25 al., FEBS letter, 475(1):17-21, 2000). Calpain has been implicated in cytoskeletal protein degradation involved in the pathophysiology of ischemia and disorders like Alzheimer's disease (Wronski et al., J. Neural transm., 107(2):145-157, 2000) and Parkinson's disease (Mouatt-Prigent et al., J. Comp. Neurol., 419:175-92, 2000), apoptosis in neural cells of rat with spinal cord injury (SCI) (Ray, Brain res., 867(1-2):80-9, 2000), cell fusibility (Kosower et al., Methods Mol Biol.,  
30 144:181-94, 2000) and other physiopathologies. Assays detecting any increased or decreased calpain levels in a cell are thus useful in the diagnosis of any of these diseases or conditions. In addition to proteolytic activities on cytoskeletal proteins and other cellular regulatory proteins, calpain-NC2 systems can also affect expression levels of genes encoding structural or regulatory proteins. Thus, the ability to detect NC2 and calpain levels is also useful for the diagnosis of an  
35 even larger number of diseases and conditions.

In another embodiment, the polynucleotides or polypeptides of the invention may be used for the detection of gametes, gametic precursor cells (such as spermatogenic stem cells), or of

specific structures within the gametes, using any technique known to those skilled in the art, including those involving the use of specific antibodies and nucleic acid probes. The ability to visualize spermatozoa generally, or the sperm acrosome in particular, has obvious utility for a number of applications, including for the analysis of infertility in patients.

5 Another embodiment of the present invention relates to a method of inhibiting calpain in a cell, the method comprising administering to the cell an amount of the present protein sufficient to inhibit calpain in the cell. Such methods can be performed in vitro or in vivo. The inhibition of calpain has numerous uses in the treatment or prevention of various diseases and conditions, for example, the pathophysiology of cerebral, myocardial, renal ischemia, platelet activation, NF-kB  
10 activation, Alzheimer's disease, Parkinson's disease, muscular dystrophy, cataract progression, cancer cachexia and rheumatoid arthritis. Such an increase can be effected in any of a number of ways, including, but not limited to administering purified protein of the invention directly to the cells, transfecting the cells with a polynucleotide encoding the protein, operably linked to a promoter; and administering to a cell a compound that increases the activity or expression of the  
15 protein of the invention. In addition, the expression or activation of the protein of the invention can be inhibited in any of a large number of ways, including using antisense oligonucleotides, antibodies, dominant negative forms of the protein, and using heterologous compounds that decrease the expression or activation of the protein. Such compounds can be readily identified, e.g. by screening candidate compounds and detecting the level of expression or activity of the  
20 protein using any standard assay. Other calpain inhibitors are also known which can be used in conjunction with the present protein, or which can be used as controls in the identification of additional inhibitors or activators of calpastatin. Such inhibitors include, but are not limited to, cerebrolysin (Wronski et al., J. Neural Transm. Suppl., 59:263-272, 2000), E-64-D (Ray et al., Brain Res., 867(1-2): 80-9, 2000), and the calpain active site inhibitor N-acetyl-leucyl-leucyl-  
25 norleucinal (Squier et al., J. Cell Physiol., 178(3): 311-319, 1999).

In still another embodiment, the protein of SEQ ID:66 or fragment thereof can be used to prevent cells from undergoing apoptosis. Specifically, any method of increasing the level or activity of the present protein in cells can be used to prevent the cells from undergoing apoptosis, in vitro or in vivo. For example, a polynucleotide encoding a protein of SEQ ID NO:66, or any  
30 fragment or derivative thereof, can be introduced into cells, e.g. in a vector, wherein the protein is expressed in the cells. Alternatively, a protein of SEQ ID NO:66 itself can be administered to cells, preferably in a formulation that leads to the internalization of the protein by the cells. Also, any compound that increases the expression or activation of the proteins within the cells can be administered. Preventing cells from undergoing apoptosis can be used for any of a large number of  
35 purposes, including, but not limited to, to prevent the death of cells being grown in culture, to prevent in a patient the apoptosis associated with any of a number of disorders, or to prevent apoptosis in cells of a patient undergoing a treatment that increases the level of cellular stress, such

as chemotherapy. Furthermore, the invention relates to methods and compositions using the protein of the invention or fragment thereof to diagnose, prevent and/or treat disorders characterized by abnormal cell proliferation and/or programmed cell death, including but not limited to cancer, immune deficiency syndromes (including AIDS), type I diabetes, pathogenic infections, cardiovascular and neurological injury, alopecia, aging, degenerative diseases such as Alzheimer's Disease, Parkinson's Disease, Huntington's disease, dystonia, Leber's hereditary optic neuropathy, schizophrenia, and myodegenerative disorders such as "mitochondrial encephalopathy, lactic acidosis, and stroke" (MELAS), and "myoclonic epilepsy ragged red fiber syndrome" (MERRF). For diagnostic purposes, the expression of the protein of the invention can be detected using any method such as Northern blotting, RT-PCR or immunoblotting methods, and compared to the expression in control individuals, wherein an increase or decrease of the level of the present protein compared to the control level indicates the presence of the disease or condition, or of a propensity for the disease or condition. For prevention and/or treatment purposes of disorders in which cell proliferation needs to be reduced and/or apoptosis increased, the expression of protein of the invention may be enhanced using any method, for example administering the purified protein to cells, transfecting the cells with a polynucleotide encoding the protein, or administering to the cells a compound that increases the expression or activity of the protein. For prevention and/or treatment purposes of disorders in which cell proliferation needs to be enhanced and/or apoptosis reduced, inhibition of endogenous expression of the protein of the invention may be achieved using any method, including triple helix and antisense strategies.

In another embodiment, inhibiting the proteins of the invention can be used to induce apoptosis in undesired cells. Such inhibition can be accomplished in any of a number of ways, including, but not limited to, using antibodies, antisense sequences, dominant negative forms of the protein, or small molecule inhibitors of the expression or activity of the proteins. Such induction of apoptosis can be used to eliminate any undesired cells, for example cancer cells, in a patient. Preferably, such inhibitors are targeted specifically to the undesired cells in the patient using standard methods.

In another preferred embodiment, the protein of the invention can be used to modulate and/or characterize fertility, including for the treatment or diagnosis of infertility, and for contraception. As NC2 is involved in the acrosomal reaction which is a required step in fertilization, over- or under-expression or activation of the present protein can be used to disrupt this reaction and thereby inhibit fertility. For example, for contraception, the expression or activation of the protein can be artificially disrupted, for example by increasing the protein level using polynucleotides encoding the protein, using the protein itself, or using activators of protein expression or activity, or by decreasing the protein level using inhibitors such as antisense oligonucleotides, antibodies, dominant negative forms of the protein, and using heterologous compounds that inhibit protein expression or activity. Similarly, the cause of infertility in many

patients can be detected by detecting the level of expression of the present protein, where an abnormal level of activity or expression of the protein indicates that a cause of infertility involves the calpain-dependent acrosomal reaction. Such a diagnosis would also point to methods of treating the infertility, e.g. by increasing or decreasing the expression or activation of the present protein in spermatozoa.

In another embodiment, the invention relates to methods and compositions using the protein of the invention or fragment thereof as a marker protein to selectively identify tissues, preferably testis, or to distinguish between two or more possible sources of a tissue sample on the basis of the level of the protein of SEQ ID NO:66 in the sample. For example, the protein of SEQ ID NO:66 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, including those described therein. Such tissue-specific antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. In such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding.

The level of antibody binding to the test sample is measured and compared to the level of binding to control cells from testis or tissues other than testis to determine whether the test sample is from testis. Similar methods can be used to specifically detect cells expressing the protein, as well as to specifically isolate cells expressing the protein or to isolate the protein itself. For example, an antibody against the protein of SEQ ID NO:66 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:66 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the protein is released from the support by contacting the support with agents which cause the protein to dissociate from the antibody.

Alternatively, the level of the protein of SEQ ID NO:66 in a test sample may be measured by determining the level of RNA encoding the protein of SEQ ID NO:66 in the test sample. RNA levels may be measured using nucleic acid arrays or using techniques such as in situ hybridization, Northern blots, dot blots or other techniques familiar to those skilled in the art. If desired, an amplification reaction, such as a PCR reaction, may be performed on the nucleic acid sample prior to analysis. The level of RNA in the test sample is compared to RNA levels in control cells from testis or tissues other than testis to determine whether the test sample is from testis. For a number of disorders listed above, particularly of inflammatory processes, expression of the genes encoding the polypeptide of SEQ ID NO:66 at significant higher or lower levels may be routinely detected in certain tissues or cell types (e.g., cancerous and wounded tissues) or bodily fluids (e.g., serum, plasma, synovial fluid, and spinal fluid) or another tissue of cell sample taken from an individual having such a disorder, relative to the standard gene expression level, i.e., the expression level in healthy tissue or bodily fluid from an individual not having the disorder.

In another embodiment, the invention relates to methods for using the protein of the invention or fragments to identify autoantibodies which indicate inflammatory processes and particularly, rheumatoid arthritis (RA), a systemic disease characterized by chronic polyarthritis and joint destruction, and in which high levels of autoantibodies directed against calpastatin have been identified. Accordingly, the present protein may be used to detect the presence and/or the localization of autoantibodies in a cell. In a typical embodiment, the protein of SEQ ID NO:66 is labeled with any detectable moiety including, but are not limited to, a fluorescent label, a radioactive atom, a paramagnetic ion, biotin, a chemiluminescent label or a label which can be detected through a secondary enzymatic or binding step. The invention further provides a method of diagnosing inflammatory processes, e.g. rheumatoid arthritis, and distinguishing such processes from other diseases.

**Protein of SEQ ID NO:68 (internal designation Clone 646607\_181-15-2-0-E2-F)**

The cDNA of Clone 646607\_181-15-2-0-E2-F (SEQ ID NO:67) encodes Benzodiazepine Receptor 2 (BZRP-R2) protein of SEQ ID NO:68, comprising the amino acid sequence:

MRLQGAIFVLLPHLGPILVWLFTRDHMSGWCEGPRMLSWCPFYKVLLL VQTAIYSVVG  
 ASYLVWKDLGGGLGWPLALPLRLYAVQLTISWTVLVLFVHNPGLALLHLLLLYGLVV  
 STALIWHPIKLAALLLPYLAWLTVTSALTYHLWRDSLCPVHQPQPTEKSD.

Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:68 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 646607\_181-15-2-0-E2-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:68 described throughout the present application also pertain to the nucleic acids included in Clone 646607\_181-15-2-0-E2-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:67, 68 and Clone 646607\_181-15-2-0-E2-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

BZRP-R2 is homologous to peripheral benzodiazepine receptor/isoquinoline binding protein (PBR/IBP) of human, bovine and murine origin (Genbank accession numbers M36035, M64520 and L17306 respectively). The 170-amino-acid protein of SEQ ID NO: 68 is similar in size and hydropathicity to known peripheral PBR/IBP benzodiazepine receptors/isoquinoline binding proteins. BZRP-R2 has five transmembrane domains at positions 3-23, 45-65, 82-102, 105-125 and 130-150. Moreover, BZRP-R2 displays a stretch of 11 amino acids (starting with V144 and ending with R154) that corresponds to a recently identified putative cholesterol recognition/interaction amino acid consensus pattern (-L/V-(X)(1-5)-Y-(X)(1-5)-R/K-) [See Li et al, Endocrinology 1998 Dec; 139 (12): 4991-7].

BZRP-R2 is capable of binding benzodiazepine and imidazopyridine derivatives, but is distinct from the GABA neurotransmitter receptor. BZRP-R2 polypeptides are most abundant in steroidogenic cells and are found primarily on outer mitochondrial membranes. BZRP-R2 is

associated with a 34-kDa pore-forming, voltage-dependent anion channel protein located on the outer/inner mitochondrial membrane contact sites. Ligands of BZRP-R2, upon binding to the receptor, simulate steroid synthesis in steroidogenic cells in vitro and in vivo. BZRP-R2 stimulates steroid formation by increasing the rate of cholesterol transfer from the outer to the inner  
5 mitochondrial membrane.

In addition to its role in mediating cholesterol movement across membranes, BZRP-R2 has been implicated in several other physiological functions, including cell growth and differentiation, chemotaxis, mitochondrial physiology, porphyrin and heme biosynthesis, immune response, and anion transport. In addition, BZRP-R2 agonists are potent anti-apoptotic compounds.

10 BZRP-R2 is associated with stress and anxiety disorders. BZRP-R2 plays a role in the regulation of several stress systems such as the HPA axis, the sympathetic nervous system, the renin-angiotensin axis, and the neuroendocrine axis. In these systems, acute stress typically leads to increases in BZRP-R2 density, whereas chronic stress typically leads to decreases in BZRP-R2 density. For example, in Generalized Anxiety Disorder (GAD), Panic Disorder (PD), Generalized  
15 Social Phobia (GSP), and Post-Traumatic Stress Disorders (PTSD), BZRP-R2 density is typically decreased. BZRP-R2 is expressed glial cells in the brain. Furthermore, BZRP-R2 expression is increased in neurodegenerative disorders and after neurotoxic and traumatic-ischemic brain damage. BZRP-R2 expression is decreased in chronic schizophrenics, suggesting that the decreased density of BZRP-R2 in the brain may be involved in the pathophysiology of  
20 schizophrenia. However, BZRP-R2 is higher than normal in autopsied brain tissue from PSE patients (Portal-Systemic Encephalopathy patients).

BZRP-R2 increases mitochondrial activity and prevents apoptosis and is therefore implicated tumor cell proliferation. BZRP-R2 is preferentially expressed in liver and breast cancers. Further, BZRP-R2 is useful as a tool/marker for detection, diagnosis, prognosis and  
25 treatment of cancer.

Many ligands have been described that bind to BZRP-R2 with various affinities. Some benzodiazepines, Ro 5-4864 [4-chlorodiazepam], diazepam and structurally related compounds, are potent and selective PBR ligands. Exogenous ligands also include 2-phenylquinoline carboxamides (PK11195 series), imidazo [1,2-a]pyridine-3-acetamides (Alpidem series),  
30 pyridazine, and isoquinilone derivatives. Some endogenous compounds, including porphyrins and diazepam binding inhibitor (DBI), bind to BZRP-R2.

In one embodiment, a preferred polypeptide of the invention comprises the amino acids of SEQ ID NO: 68 from position 144 to 154: VTSALTYHLWR. Further preferred fragments of BZRP-R2 comprise the epitope: ALPLRLYAV or fragments thereof. In another embodiment, the  
35 subject invention provides a polypeptide comprising the sequence of SEQ ID NO: 68. Other preferred polypeptides of the invention include biologically active fragments of SEQ ID NO: 68. Biologically active fragments of the protein of BZRP-R2 have any of the biological activities

described herein. In another embodiment, the polypeptide of the invention is encoded by clone 646607 215-15-5-0-B11-F.

A preferred embodiment of the invention is a method of screening for compounds that modulate the expression of BZRP-R2. This method comprises the steps of i) contacting a cell with  
5 a test compound and ii) comparing the level of BZRP-R2 polypeptides in a cell after exposure to the test compound to that of an untreated control cell. The level of BZRP-R2 polypeptides may be inferred by detecting mRNA for BZRP-R2 by methods common to the art such as Northern blotting or RT-PCR. The level of BZRP-R2 polypeptides may also be detected by antibody-based methods common to the art such as Western blotting or immunofluorescence. Test compounds  
10 that increase BZRP-R2 expression are useful as agonists, as discussed herein. Test compounds that decrease BZRP-R2 expression are useful as antagonists, as discussed herein.

Antagonists of BZRP-R2 include agents which decrease the levels of expressed mRNA encoding the protein of SEQ ID NO: 68. These include, but are not limited to, RNAi, one or more ribozymes capable of digesting the protein of the invention, or antisense oligonucleotides capable  
15 of hybridizing to mRNA encoding BZRP-R2. Antisense oligonucleotides can be administered as DNA, RNA, as DNA entrapped in proteoliposomes containing viral envelope receptor proteins [Kanoda, Y. et al. (1989) Science 243: 375, which disclosure is hereby incorporated by reference in its entirety] or as part of a vector which can be expressed in the target cell to provide antisense DNA or RNA. Vectors which are expressed in particular cell types are known in the art.  
20 Alternatively, the DNA can be injected along with a carrier. A carrier can be a protein such as a cytokine, for example interleukin 2, or polylysine-glycoprotein carriers. Carrier proteins, vectors, and methods of making and using polylysine carrier systems are known in the art. Alternatively, nucleic acid encoding antisense molecules may be coated onto gold beads and introduced into the skin with, for example, a gene gun [Ulmer, J.B. et al. (1993) Science 259:1745, which disclosure is  
25 hereby incorporated by reference in its entirety].

A preferred embodiment of the invention is a method of screening for compounds that bind to BZRP-R2 polypeptides. Such compounds are useful for developing agonists and antagonists of BZRP-R2 activity. This method comprises the steps of: i) contacting a BZRP-R2 polypeptide or fragment thereof with a test compound under conditions that allow binding to occur and ii)  
30 detecting binding of said test compound. Binding may be detected by any method common to the art such as competition with a labeled antibody specific for BZRP-R2 or by direct labeling of each test substance. In one example of such a method, a polynucleotide encoding a BZRP-R2 polypeptide or a biologically active fragment thereof is transformed into a eukaryotic or prokaryotic host cell. The transformed cells may be viable or fixed. Drugs or compounds which  
35 are candidates for binding BZRP-R2 polypeptides are screened against such transformed cells in binding assays well known to those skilled in the art. Alternatively, assays such as those taught in Geysen H. N., WO Application 84/03564, published on Sep. 13, 1984, and incorporated herein by

reference in its entirety, may be used to screen for peptide compounds which demonstrate binding affinity for BZRP-R2 polypeptides or fragments thereof. In another embodiment, competitive drug screening assays using neutralizing antibodies specifically compete with a test compound for binding to BZRP-R2 polypeptides or fragments thereof. Preferred test compounds are those included in the benzodiazepine class, such as diazepam (i.e., valium), triazolobenzodiazepine, and adinazolam, as well as modified versions thereof. Further preferred test compounds are in the imidazo pyridine and isoquinilone classes.

A variety of drug screening techniques may be employed. In this aspect of the invention, BZRP-R2 polypeptide or biologically active fragments thereof, may be free in solution, affixed to a solid support, recombinantly expressed on or chemically attached to a cell surface, or located intracellularly. The formation of binding complexes between BZRP-R2 polypeptides or biologically active fragments thereof, and the compound being tested, may then be measured as described.

Another embodiment of the subject invention provides compositions and methods of selectively modulating the activity of the protein of the invention. Modulation of BZRP-R2 allows for the successful prevention, treatment, or management of disorders or biochemical abnormalities associated with BZRP-R2. Agonist compounds are those that increase the amount of BZRP-R2 polypeptides in a cell or increase the biological activity of BZRP-R2. A preferred embodiment of the invention is a method of screening for agonists that bind to BZRP-R2 comprising the steps of: i) screening for test substances that bind to BZRP-R2, as described above and ii) detecting BZRP-R2 biological activity. Preferably, this method is accomplished in an intact cell. Further preferably, the cell is a steroidogenic cell such as a testicular or ovarian cell. Preferably, the biological activity of BZRP-R2 is determined by measuring the concentration of steroid hormones released from the cell before and after exposure to the test substance. Agonists of BZRP-R2 will increase the release of steroid hormones from the cell. Antagonist compounds are those that decrease the amount of BZRP-R2 polypeptides in a cell or decrease the biological activity of BZRP-R2. Another preferred embodiment of the invention is a method of screening for antagonists that bind to BZRP-R2 comprising the steps of: i) screening for test substances that bind to BZRP-R2, as described above and ii) detecting BZRP-R2 biological activity. Preferably, this method is accomplished in an intact cell. Further preferably, the cell is a steroidogenic cell such as a testicular or ovarian cell. Preferably, the biological activity of BZRP-R2 is determined by measuring the concentration of steroid hormones released from the cell before and after exposure to the test substance. Antagonists of BZRP-R2 will decrease the release of steroid hormones from the cell.

Antagonists, able to reduce or inhibit the expression or the activity of the protein of the invention, are useful in the treatment of diseases associated with elevated levels of BZRP-R2, increased cell proliferation or reduced apoptosis, and increased cholesterol transport. Thus, the

subject invention provides methods for treating a variety of diseases or disorders, including but not limited to cancers, especially liver and breast cancer, and portal-systemic encephalopathy.

Increased cholesterol transport into the mitochondria of steroidogenic cells results in higher than normal production of steroid hormones such as progesterone, testosterone, and estrogen.

- 5 Abnormally high levels of steroid hormones lead to disruption of adrenocortical feedback mechanisms and underproduction of trophic hormones from the hypothalamus and pituitary. Inhibition of BZRP-R2 and steroidogenesis may increase levels of trophic hormones such as gonadotropin-releasing hormone.

- Alternatively, the subject invention provides a method of treating diseases or disorders
- 10 associated with decreased levels of BZRP-R2 polypeptides and decreased steroid hormone release with an agonist thereof. Such method comprises the step of contacting a cell with a BZRP-R2 agonist. This method comprises the step of contacting a cell with an agonist of BZRP-R2. Thus, the subject invention provides methods of treating disorders including, but not limited to, schizophrenia, chronic stress, GAD, PD, GSP and PTSD. Other disorders which may be treated by
- 15 agonists of BZRP-R2 include those associated with decreases in cell proliferation, e.g. developmental retardation. Furthermore, because BZRP-R2 is able to transport cholesterol into cells, BZRP-R2 agonists may also be used to increase cholesterol transport into cells. Diseases associated with cholesterol transport deficiencies include lipoidal adrenal hyperplasia, ovarian cysts, abnormal lipid deposits in steroidogenic cells. Disorders that reflect a requirement for
- 20 cholesterol for myelin and myelination, include Alzheimer's disease, multiple sclerosis, spinal cord injury, and brain development neuropathy. The methods of treating disorders associated with decreased levels of BZRP-R2 may be practiced by introducing agonists which stimulate the expression or the activity of BZRP-R2.

- Additionally, disorders resulting from defective mitochondrial activity may be treated with
- 25 an agonist to BZRP-R2. Defective mitochondrial activity may alternatively or additionally result in the generation of highly reactive free radicals that have the potential of damaging cells and tissues. These free radicals may include reactive oxygen species (ROS) such as superoxide, peroxynitrite and hydroxyl radicals, and other reactive species that may be toxic to cells and cause apoptosis. For example, oxygen free radical induced lipid peroxidation is a well-established
- 30 pathogenic mechanism in central nervous system (CNS) injury such as that found in a number of degenerative diseases, and in ischemia (i.e., stroke). Diseases associated with altered mitochondrial function and apoptosis include: Alzheimer's Disease, diabetes mellitus, Parkinson's Disease, Huntington's disease, dystonia, Leber's hereditary optic neuropathy, schizophrenia, mitochondrial encephalopathy, lactic acidosis, and stroke.

- 35 A further preferred embodiment includes a method of inhibiting apoptosis of cells in culture. This method comprises the step of contacting a cell in culture with an agonist to BZRP-R2. Such methods are useful for culturing cells that are notoriously undergo apoptosis, such as

primary neurons and lymphocytes.

In one embodiment, the level of BZRP-R2 in a cell may be increased by introducing nucleic acids encoding a BZRP-R2 polypeptide or biologically active fragment thereof into a targeted cell type. Vectors useful in such methods are known to those skilled in the art, as are  
5 methods of introducing such nucleic acids into target tissues.

Antibodies or other polypeptides capable of reducing or inhibiting the activity of BZRP-R2 may be provided as in isolated and substantially purified form. Alternatively, antibodies or other polypeptides capable of inhibiting or reducing the activity of BZRP-R2 may be recombinantly expressed in the target cell to provide a modulating effect. In addition, compounds which inhibit  
10 or reduce the activity of BZRP-R2 may be incorporated into biodegradable polymers being implanted in the vicinity of where drug delivery is desired. For example, biodegradable polymers may be implanted at the site of a tumor or, alternatively, biodegradable polymers containing antagonists/agonists may be implanted to slowly release the compounds systemically. Biodegradable polymers, and their use, are known to those of skill in the art (see, for example,  
15 Brem et al. (1991) J. Neurosurg. 74:441-446, which disclosure is hereby incorporated by reference in its entirety).

In another embodiment, the invention provides methods and compositions for detecting the level of expression of the mRNA encoding the protein of the invention. Quantification of mRNA levels of BZRP-R2 may be useful for the diagnosis or prognosis of diseases associated with an  
20 altered expression of the protein of the invention. Assays for the detection and quantification of the mRNA encoding BZRP-R2 are well known in the art (see, for example, Maniatis, Fitch and Sambrook, Molecular Cloning; A Laboratory Manual (1982), or Current Protocols in Molecular Biology, Ausubel, F.M. et al. (Eds), Wiley & Sons, Inc., disclosures of which are hereby incorporated by reference in their entirety).

Polynucleotides probes or primers for the detection of BZRP-R2 mRNA can be designed from the cDNA of SEQ ID NO: 67. Methods for designing probes and primers are known in the art. In another embodiment, the subject invention provides diagnostic kits for the detection of the mRNA of the protein of the invention in cells. The kit comprises a package having one or more containers of oligonucleotide primers for detection of the protein of the invention in PCR assays or  
30 one or more containers of polynucleotide probes for the detection of the mRNA of the protein of the invention by in situ hybridization or Northern analysis. Kits may, optionally, include containers of various reagents used in various hybridization assays. The kit may also, optionally, contain one or more of the following items: polymerization enzymes, buffers, instructions, controls, or detection labels. Kits may also, optionally, include containers of reagents mixed  
35 together in suitable proportions for performing the hybridization assay methods in accordance with the invention. Reagent containers preferably contain reagents in unit quantities that obviate measuring steps when performing the subject methods.

In another embodiment, the invention relates to methods and compositions for detecting and quantifying the level of the protein of the invention present in a particular biological sample. These methods are useful for the diagnosis or prognosis of diseases associated with altered levels of the protein of the invention. Diagnostic assays to detect the protein of the invention may

5 comprise a biopsy, in situ assay of cells from organ or tissue sections, or an aspirate of cells from a tumor or normal tissue. In addition, assays may be conducted upon cellular extracts from organs, tissues, cells, urine, or serum or blood or any other body fluid or extract.

Assays for the quantification of BZRP-R2 polypeptides may be performed according to methods well known in the art. Typically, these assays comprise the steps of: contacting the

10 sample with a ligand of the protein of the invention or an antibody (polyclonal or monoclonal) that specifically recognizes the protein of the invention or a fragment thereof and detecting the complex formed between the protein of the invention present in the sample and the ligand or antibody. Fragments of the ligands and antibodies may also be used in the binding assays, provided these fragments are capable of specifically interacting with BZRP-R2 polypeptides. Further, ligands and

15 antibodies which bind to BZRP-R2 may be labeled according to methods known in the art. Labels which are useful in the subject invention include, but are not limited to, enzymes labels, radioisotopic labels, paramagnetic labels, and chemiluminescent labels. Typical techniques are described by Kennedy, J. H., et al. (1976) Clin. Chim. Acta 70:1-31; and Schurs, A. H. et al. (1977) Clin. Chim. Acta 81: 1-40, disclosures of which are hereby incorporated by reference in

20 their entireties.

The subject invention also provides methods and compositions for the identification of metastatic tumor masses. In this aspect of the invention, the polypeptide or antibody that specifically binds a BZRP-R2 polypeptide or fragment thereof may be used as a marker for the identification of the metastatic tumor mass. Metastatic tumors which originated from the breast or

25 liver may overexpress BZRP-R2 polypeptides, whereas newly forming tumors, or those originating from other tissues are not expected to bear BZRP-R2.

**Protein of SEQ ID NO:70 (Internal designation Clone 229654\_114-049-1-0-F12-F (cFS))**

The cDNA of Clone 229654\_114-049-1-0-F12-F (SEQ ID NO:69) encodes the 787 amino acid long polypeptide called LAP of SEQ ID NO:70 comprising the amino acid sequence :

- 5 EGSTQTYAGQTRSESSSQADTSKSKSEDSAEAYTSRSKSQDSTQTQSSSN. Accordingly, it  
 will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:70 described  
 throughout the present application also pertain to the polypeptides encoded by the nucleic acids  
 included in Clone 229654\_114-049-1-0-F12-F. In addition, it will be appreciated that all  
 characteristics and uses of the polynucleotides of SEQ ID NO:69 described throughout the present  
 10 application also pertain to the nucleic acids included in Clone 229654\_114-049-1-0-F12-F. A  
 preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:69,  
 SEQ ID NO:70, and Clone 229654\_114-049-1-0-F12-F. Also preferred are polypeptide fragments  
 having a biological activity as described herein and the polynucleotides encoding the fragments.

- LAP, the protein of SEQ ID NO:70, is a new member of the ADAM (A Disintegrin And  
 15 Metalloprotease domain) family of proteins. The gene for Clone 229654.cFS is located on  
 chromosome 8 and is expressed in tissues including liver, adipose and testis.

- LAP, as an ADAM family member is a membrane-anchored cell surface protein. The  
 members of this family form a large group of cell surface adhesion molecules and proteases whose  
 name describes the two domains that these proteins share with their closest relatives, the PIII class  
 20 of snake venom metalloproteinases (SVMPS). The ADAM proteases fall with the SVMPS within  
 the adamalysin/reprolysin subfamily of Zinc-dependent metalloproteinases. ADAMs have also  
 been referred to as MDCs (metalloproteinase/disintegrin/cysteine-rich), cellular disintegrins, and  
 metalloproteinase-desintegrins.

- These proteins have been isolated from a wide range of organisms ranging from yeast,  
 25 worm, flies, frogs and mammals. Expression studies have shown that while some ADAMS have  
 wide tissue expression, some have their expression restricted to one tissue.

- The ADAM proteins have been shown to function in cell-cell interaction, cell-signaling,  
 and in the processing of the ectodomains of membrane-anchored proteins and have been implicated  
 in diverse biological processes, including sperm-egg binding and fusion, myoblast fusion, protein-  
 30 ectodomain shedding of cytokines, cytokine receptors, adhesions and other extracellular protein  
 domains. Furthermore, they have been shown to be necessary for proper axonal guidance, neural  
 and wing development in *Drosophila*, vulval development in *Caenorhabditis elegans*, and epithelial  
 maturation and skin and hair development in the mouse.

- Structurally, LAP has an N-terminal signal sequence (MFRLWLLLAGLCGLLAS), a  
 35 prodomain  
 (HLKQRYFLTDNFMIIYLYNQ GSMNTYSSDIQTQCY YQGNIEEYPDSMVTLS TCSGLRGILQ  
 FENVSYGIEPLESAVEFQHVLHKLKNEDNDIAIFIDRSLKEQPMDDNIFISEKS) that has been

shown to maintain the enzyme in an inactive state, followed by a metalloprotease domain

YVFCGWRNLICGRLVCTYPTRKPFHQENGDVYAFVRDVC) that also have adhesion activity, an EGF-like domain

(CDIGRVCVNRECVESRIIKASAHVCSQQCSGHGVCDNRNKCHCSPGYKPPNC) important for substrate recognition, a transmembrane domain (TWLLGFLIALPILIVTTAIVL) and a

- 15 cytoplasmic tail

(ARKQLKNWFAKEEEFPSSSEKSEGSTQTYASQSSSEGSTQTYAGQTRSESSSQADTSKSKS  
EDSAEAYTSRKSQDSTQTQSSSN) that has been shown in many ADAMs to contain SH3 binding sites and which might be important for cell signaling.

Interestingly, the cytoplasmic C-terminal domain of the LAP protein does not contains any

- 20 SH3 binding sites but it ends by a 69 amino acid region rich in serine/threonine residues (36% of serine residues;

SSESKSEGSTQTYASQSSSEGSTQTYAGQTRSESSSQADTSKSKSEDSAEAYTSRKSQDST  
QTQSSS).

- LAP contains both a disintegrin-like and a metalloprotease domain, and has both cell  
25 adhesion and protease activities. However, LAP lacks the catalytic site consensus sequence in its metalloprotease domain (QMLALSLGISYD). LAP, like fertilin beta another catalytically inactive protease, is processed on the sperm cell surface during sperm maturation in the epididymus yielding mature protein that retains disintegrin domain on fertilization-competent sperm.

Preferred LAP polypeptides for uses in the methods described below include the

An embodiment of the invention is directed to a method to screen for molecules which block the interaction of LAP with the cell-surface receptors on the oocyte surface comprising the steps of contacting sperm with said molecule to be screen, contacting the sperm with the oocyte, and disrupting sperm-oocyte binding.

25 A preferred embodiment of the invention is directed to a method of inhibiting sperm-oocyte interaction by blocking the LAP interaction with the oocyte cell surface comprising the steps of contacting sperm with a blocking molecule, as identified in a screen, which inhibits or blocks the LAP-oocyte interaction. Preferred agents include antibodies directed to LAP-disintegrin domain.

30 LAP is a plasma membrane-anchored protein having adhesion and cell signaling activities in liver cells as well as in adipocytes. More specifically, it is believed that the mature LAP protein interacts, via its extracellular domain, with as yet unidentified integrins and other proteins present at the surface of neighbouring cells, while its cytoplasmic serine-rich domain is involved in signaling events by interacting with cytoplasmic or plasma membrane-associated proteins that  
 35 interact with serine-rich domains. More over, as serine and threonine residues are both phosphorylatable residues, the signaling activity of the LAP protein is regulated by phosphorylation/dephosphorylation events of specific serine and or threonine residue(s) present on

this domain.

In a further embodiment, polyclonal or monoclonal antibodies directed against polypeptides of the invention are used in methods to reduce or inhibit cell-cell interactions between cells in vitro, preferably liver or adipose cells. A preferred method of reducing or inhibiting cell-cell interactions comprises the steps: i) contacting the cells with a composition comprising an inhibitory-effective amount of an antibody directed against polypeptides of the invention, preferably a monoclonal antibody directed against the disintegrin-like domain or a monoclonal antibody directed against the cysteine-rich domain.

A further embodiment is directed to a method of blocking or inhibiting the interaction of LAP with at least one of its binding-partners comprising the steps: i) contacting cells with a blocking-effective amount of a polypeptide fragment of the invention comprising an extracellular domain of LAP. Preferred extracellular domains to be used in said methods of blocking the interaction of LAP and a binding partner include the disintegrin-like domain of LAP and the cysteine-rich domain of LAP. Preferred synthetic peptides to be used in compositions of said methods have amino acid sequences comprising CRPKAHPECDIAENC or CGNGRLEGNEICDCG, or a combination thereof.

**Protein of SEQ ID:72 (Internal designation Clone 338116\_174-1-1-0-B10-F)**

The cDNA of Clone 338116\_174-1-1-0-B10-F (SEQ ID NO:71) encodes the protein of SEQ ID NO:72, herein referred as Short Histone Deacetylase (SHDAC), comprising the amino acid sequence:

MGPHLHLCLCVPDLRSLRVCVSLWSVHHRPHESLAREEALTALGKLLYLLDGMLDGQVN  
SGIAATPASAAAATLDVAVRRGLSHAAQRLLCVALGQLDRPPDLAHDGRSLWLNIRGKE  
AAALSMFHVSTPLPVM TGGFLSCILGLVLPLAYGFQPDVLVALGPGHGLQGPHXALLAA  
MLRGLAGGRVLALLEENSTPQLAGILARVLNGEAPPSLGSSVASPEDVQALMYLRGQLE  
PQWKMLQCHPHLVA, is encoded by the cDNA clone 338116\_174-1-1-0-B10-F (SEQ ID:71). The protein of SEQ ID NO:72 is a novel variant of histone deacetylase (HDAC). Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:72 described throughout the present application also pertain to the polypeptide encoded by a nucleic acid included in clone 338116\_174-1-1-0-B10-F. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:71 described throughout the present application also pertain to the nucleic acid included in clone 338116\_174-1-1-0-B10-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:71, SEQ ID NO:72, and Clone 338116\_174-1-1-0-B10-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID:72 contains one potential transmembrane segment (position 130 to 150), and a signal peptide (position 1: MGPHLHLCLCVPDLRSL). The protein of SEQ ID:72 is highly expressed in placenta and salivary glands.

- Histone deacetylase (HDAC) proteins comprise a family of related proteins that act in conjunction with histone acetyl-transferase proteins to modulate chromatin structure and transcriptional activity via changes in the acetylation status of histones. HDACs remove acetyl groups from histones by hydrolysis [Davie, J.R. *Curr. Opin. Genet. Dev.* 8, 173-178 (1998)],
- 5 thereby causing local chromatin condensation and decreasing the accessibility of particular DNA regions for RNA polymerase complexes. In fact, transcriptionally active chromatin correlates with histone hyperacetylation [Grundstein M. *Nature* 389:349-352 (1997)], and it has been suggested that histone acetyltransferases promote transcription while histone deacetylases act as repressors and transcriptional silencer [Doetzlhofer A. et al., *Mol. Cell. Biol.* 19:5504-5511(1999)].
- 10 Histone deacetylase proteins belong to a superfamily of zinc metalloenzymes with a conserved 380 residue catalytic domain [Finnin, M.S. et al., *Nature* 401:188-193(1999)]. Histone deacetylases are found in high-molecular-weight complexes associated with adapter proteins like SIN3, RbAp46/48, SAP18, SAP30, and nuclear corepressors like N-CoR, SMRT, and SUN-CoR [Alland, L. et al., *Nature* 387:49-55 (1997); Heinzel, T. et al., *Nature* 387:43-48 (1997); Laherty,
- 15 C.D. et al., *Cell* 89: 349-356 (1997); Nagy, L.H. et al., *Cell* 89:373-380 (1997); Zhang, W. et al., *EMBO J.* 17:3155-3167 (1997); Zhang; Y. et al., *Cell* 89:357-364 (1997); Knoepfker, P.S. & Eisenman, R.N. *Cell* 99:447-450 (1999)].

- Histone deacetylases are recruited to specific promoters by mammalian transcriptions factors such as Matrix-associated Deacetylase (Mad) [Sommer, A. et al., *Curr. Biol.* 7 :357-365
- 20 (1997)], YY1 [Yang, W.M. *Proc. Natl. Acad. Sci. USA* 93:12845-12850 (1996)], hormone-dependent nuclear receptor [Nagy, L.H. et al., *Cell* 89:373-380 (1997)], MeCP2 [Jones, P.L. et al., *Nat. Genet.* 19:187-191 (1998)], CBF [Kao, H.Y.P. et al., *Genes Dev.* 12:2269-2277 (1998)], Retinoblastoma protein (Rb) [Brehm, A. et al., *Nature* 391:597-601 (1998)], *groucho* [Chen, G. et al., *Genes Dev.* 13:2218-2230 (1999)] B-lymphocyte-induced maturation protein [Yu, J. et al.,
- 25 *Mol. Cell. Biol.* 20:2592-2603 (2000)] and related pocket proteins [Ferreira et al., *Proc. Natl. Acad. Sci. USA* 95:10493-10498 (1998)] for repression. The recruitment of human histone deacetylases by PZLF (promyelocytic leukaemia zinc finger), PML (promyelocytic leukaemia), and ETO fusion proteins can interfere with differentiation of hematopoietic precursor cells in acute promyelocytic leukemia [Lin, R.J. et al., *Nature* 311:811-815 (1996); David, G.L. et al., *Oncogene*
- 30 16:2549-2556 (1998); Grignani, F.S. et al., *Nature* 391:815-818 (1998); Guidez et al., *Blood* 91:2634-2642 (1998)].

- Several drugs have been identified as acting upon histone acetylation. Some examples are: trichostatin A (TSA), apicidin (antiprotozoal agent), superoylanilide hydroxamic acid (SAHA), cyclic hydroxamic acid-containing peptide (CHAP) 1, FR901228 (a potent antitumor), CBHA (m-
- 35 carboxycinnamic acid bis-hydroxamide), trapoxin, MS-275 (antitumor), pyroxamide (suberoyl-3-aminopyridineamide hydroxamic) acid and phenyl butyrate. Such drugs cause major alterations in cellular activity, including the induction of cellular differentiation and apoptosis [Medina, V. et al.,

- Cancer Res. 57:3697-3707 (1997); Richon, V.M. et al., Proc. Natl. Acad. Sci. U.S.A. 95:3003-3007 (1998); Sambucetti, L.C. et al., J. Biol. Chem. 274:34940-34947 (1999); Buter, L.M. et al., Clin. Cancer Res. 7:962-970 (2001); Coffey, D.C. et al., Cancer Res. 61:3591-3594 (2001); Colletti, S.L. et al., Bioorg. Med. Chem. Lett. 11:107-111 (2001); Furumai, R. et al., Proc. Natl. Acad. Sci. USA 98:87-92 . (2001); Lee, B.I. et al., Cancer Res. 63:931-934 (2001)].

The protein of SEQ ID NO:72 is a novel splice and polymorphism variant of histone deacetylase and, as such, plays a role in transcription, chromosome stability, cell cycle progression, gene silencing, lymphocyte and muscle differentiation, aging, regulation of neuronal phenotype, DNA replication and the response to DNA damage. Particularly, the protein of the invention may deacetylate substrates, preferably acetylated histones, either directly or indirectly as enzymes cofactors. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:72 from positions 29 to 252. Also preferred are fragments of SEQ ID NO:72 having a biological activity as described therein and the polynucleotides encoding the fragments. The deacetylation activity of the protein of the invention or fragment thereof may be assayed using any of a number of methods known to those skilled in the art.

The invention relates to methods and compositions using the protein of SEQ ID NO:72 or fragment thereof to inhibit or modulate cellular transcriptional activity, thereby modulating cellular differentiation. Specifically, as histone deacetylases play a role in inhibiting transcription associated with differentiation, then an increase in the activity or expression of the protein can be used to inhibit differentiation. The ability to inhibit differentiation has a number of uses, for example during the cultivation of undifferentiated pluripotent cells to maintain the cultured cells in an undifferentiated state until the need for a given cell type arises (in cases of grafts for instance). For example, the histone deacetylase of the invention may be used to arrest a population of non-neoplastic cells grown in vitro in the G1 or G2 phase of the cell cycle. Such synchronization allows, for example, the identification of gene and/or gene products expressed during the G1 or G2 phase of the cell cycle. Such a synchronization of cultured cells may also be useful, for testing the efficacy of a new transfection protocol, where transfection efficiency varies and is dependent upon the particular cell cycle phase of the cell to be transfected. Use of the histone deacetylase of the invention allows the synchronization of a population of cells, thereby adding detection of enhanced transfection efficiency. The level of the protein activity or expression can be increased in any of a number of ways, including by introducing a polynucleotide encoding the protein into cells, by administering the protein itself to cells, or by administering to cells a compound that increases protein activity or expression. Alternatively, the expression or activation of the protein of the invention can be inhibited in any of a large number of ways, including using antisense oligonucleotides, antibodies, dominant negative forms of the protein, and using heterologous compounds that decrease the expression or activation of the protein. Such compounds can be readily identified, e.g. by screening candidate compounds and detecting the level of expression or

activity of the protein using any standard assay. The ability to promote differentiation has many uses, including in the treatment or prevention of cancer, as cancer cells are often in a relatively undifferentiated state, and cellular differentiation typically accompanies by growth arrest.

In another embodiment, eukaryotic cells are genetically engineered in order to express the protein of the invention or fragment thereof under specific conditions in order to prevent and/or treat disorders characterized by abnormal cell proliferation and/or programmed cell death, including but not limited to cancer, immune deficiency syndromes (including AIDS), type I diabetes, pathogenic infections, cardiovascular and neurological injury, alopecia, aging, degenerative diseases such as Alzheimer's Disease, Parkinson's Disease, Huntington's disease, dystonia, Leber's hereditary optic neuropathy, schizophrenia, and myodegenerative disorders such as "mitochondrial encephalopathy, lactic acidosis, and stroke" (MELAS), and "myoclonic epilepsy ragged red fiber syndrome" (MERRF). For example, a vector capable of expressing the protein of SEQ ID NO: 72, or biologically active fragments thereof, can be administered to a subject to treat or prevent disorders including, but not limited to, those described above. Alternatively, the vector can encode a variant, or biologically active fragment of the variant protein. Multiple vectors encoding any combination of SEQ ID NO: 72, variants, and/or biologically active fragments of SEQ ID NO: 72 and/or variants can be administered to a subject.

The invention relates to methods and compositions using the protein of the invention or fragment thereof to deacetylate substrates, alone or in combination with other substances, for example, but not limited to silence specific target genes. Acetylated substrates used in such methods are preferably acetylated histones and acetyltransferases. For example, the protein of the invention or fragment thereof is added to a sample containing a substrate in conditions allowing deacetylation, and allowed to catalyze the deacetylation of the substrate. In a preferred embodiment, the deacetylation is carried out using a standard assay such as those described in Landry and collaborators [Landry et al., Proc. Natl. Acad. Sci. 97:5807-5811 (2000), the disclosure of which is incorporated by reference in its entirety]. Deacetylated histones obtained by this method may be mixed with purified naked DNA (plasmid preparations for example) in order to reconstitute chromatin-like structures *in vitro*. Such structures are of great interest in the study of enzymatic factors involved in transcription and replication. Natural transcription factors are unable to enter the condensed chromatin, and the gene function is effectively switched-off. Also, the chromatin condensation constitutes a valuable parameter in the assessment of male fertility, completely independent of conventional sperm parameters [Hammadeh, M.E., et al., Arch Androl;46(2):99-104 (2001)].

Another embodiment of the present invention relates to composition and methods of using the protein of the invention or fragment thereof to screen for inhibitors and activators of deacetylase activity. Such deacetylase inhibitors are of great potential as new drugs due to their ability to influence transcriptional regulation and to induce apoptosis or differentiation in cancer

cells [Marks P.A. et al., Clin. Cancer Res. 7:759-760 (2001)], and also as antiproliferative reagents involved in antiprotozoal, antifungal, phytotoxic and antiviral applications [Meinke, P.T. & Liberator, P., Curr. Med. Chem. 8:211-235 (2001)]. In one such embodiment, the protein of the invention is contacted *in vitro* with a fluorescently labeled acetylated substrate as well as a test agent, and the activity of the protein is detected, wherein a difference in the activity of the protein in the presence of the test agent in comparison to the activity in the absence of the test agent indicates that the test agent is a modulator of the protein. Suitable substrates include, e.g., aminocoumarin derivative of an acetylated lysine, which can be quantitated using a reverse-phase HPLC-system with a fluorescence detector [see, e.g., Hoffmann et al., Nucl. Acids Res. 27:2057-2058 (1999); Hoffmann et al., Pharmazie 55:601-606 (2000); the disclosures of each of which are incorporated herein in their entireties].

In another preferred embodiment, the polynucleotides of SEQ ID:71, polypeptides of SEQ ID:72 or antibodies to the polypeptide of the present invention may also be used in screening methods for detecting an abnormally decreased or increased level of polypeptides or mRNA, as well as to detect the effect of added compounds on the production of the present mRNA and polypeptide in cells. Abnormal activity of our protein is associated with accelerated aging syndromes such as Cochin's syndrome, Ataxia telangiectasia and Werner's syndrome as well as age-associated diseases as well as "early onset" forms of diseases associated with old age such as dementia and Parkinson's disease. Decreased or increased expression can be measured, for example, at the RNA level using any of the methods known in the art for the quantification of polynucleotides, such as nucleic acid amplification methods including PCR and RT-PCR, as well as RNase protection, Northern blotting and other hybridization methods. Expression can also be detected using assays to determine levels of the present protein, such as ELISA assays.. These methods can also be used to discover agents which inhibit or enhance the production of polypeptide in cells or tissues. Examples of potential polypeptide inhibitors include antibodies, oligonucleotides, heterologous proteins, or small molecule inhibitors of the present protein.

Another embodiment of the invention relates to methods of preparing antibodies that selectively bind to the protein of the invention or fragment thereof. Such antibodies may be used, for example, in co-immunoprecipitation procedures that enrich for chromatin fragments containing binding sites for the protein of the invention. This method may identify genes or regions of the human genome silenced by the deacetylase activity of the protein of the invention and also proteins which interact with the compacted form of the chromatin like RCC1 (regulator of chromosome condensation) [Renault, L. et al., Cell, 105:245-255 (2001)]. For example, in one method, antibodies that selectively bind to HDAC are coupled to protein A or protein G sepharose beads and added to samples containing fragments of native chromatin under conditions amenable to immunoprecipitation, and the DNA fragments co-precipitated with HDAC are extracted and subcloned. These DNA fragments can then be either sequenced and/or used as probes to screen

genomic libraries [Gould et al., Nature 348:308-312 (1990), the disclosure of which is incorporated herein by reference in its entirety].

In another embodiment, the invention relates to methods and compositions using the protein of the invention or fragment thereof as a marker protein to selectively identify tissues, such as salivary gland or placenta, or to distinguish between two or more possible sources of a tissue sample on the basis of the level of the protein of SEQ ID NO:72 in the sample. For example, the protein of SEQ ID NO:72 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art, and the antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. Typically, in such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. In one embodiment, the level of antibody binding to the test sample is measured and compared to the level of binding expected from control cells from salivary gland and placenta, or tissues other than salivary gland and placenta, to determine whether the test sample is from salivary gland and placenta. Such methods may also be performed in conjunction with other, independent methods for determining cellular identity. Similar methods can be used to specifically detect cells expressing the protein, as well as to specifically isolate cells expressing the protein or to isolate the protein itself. For example, an antibody against the protein of SEQ ID NO:72 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:72 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the protein is released from the support by contacting the support with agents which cause the protein to dissociate from the antibody.

A preferred embodiment of the invention relates to compositions or methods using the protein of SEQ ID NO:72 or fragment thereof to diagnose, treat and/or prevent disorders caused by the expression of genes whose transcription is regulated by the extent of local chromatin condensation. The number of pathologies and conditions that could be treated by the protein of the invention is potentially huge and unlimited. Favored disorders linked to dysregulation of gene transcription such as cancer and other disorders relating to abnormal cellular differentiation, proliferation, or degeneration, including leukemia, lymphomas, prostate hypertrophy, kidney diseases, kidney failures, viral infection especially HIV and viral hepatitis (i.e. expression of viral proteins), metabolic diseases such as obesity and a number of inflammatory diseases, for example due to interleukin over-expression. For diagnostic purposes, the expression of the protein of the invention can be investigated using any method, for example Northern blotting, RT-PCR or immunoblotting methods, and compared to the expression in control individuals. For prevention and/or treatment purposes, the expression of the protein of the invention may be enhanced,

inhibited, or otherwise altered in a patient using any of a number of methods, including gene therapy methods, or by administering a compound that enhances or inhibits the expression or activity of the protein.

In one embodiment, the present invention provides a method for inhibiting the proliferation of a cell, the method comprising introducing into the cell the protein of the invention, linked to a heterologous protein domain that specifically targets the present protein to a cell-proliferation-regulating gene, wherein the targeting of the present protein to the gene results in local chromatin condensation and an inhibition in the expression of the gene. Cell-fusion proteins containing both the deacetylase activity and the specific DNA binding domain are obtained by methods of molecular biology well known to those skilled in the art. In one embodiment, such fusion proteins are introduced into the cell by transfecting the cell with a polynucleotide encoding the fusion protein, wherein the fusion protein is expressed in the cell. Such polynucleotides, e.g. in the form of expression vectors, which can thus be used, e.g., for gene therapy to treat or prevent cancer, metabolic disorders, aging and any disorder where a gene is over-expressed in association with local chromatin decondensation. Such recombinant cDNA may be introduced, for example, using in any vector, viral or non-viral, and viral vectors can be but not limited to retroviral, adenoviral, and adeno-associated vectors, which have been used in cancer therapy (Alemany et al., Nat. Biotechnol. 18:723-727 (2000)). Another approach is to administer a therapeutic amount of a polypeptide of SEQ ID:72, preferably in combination with a suitable pharmaceutical carrier. Such carriers include, but are not limited to, saline, buffered saline, dextrose, water, glycerol, ethanol and combinations thereof.

In another embodiment, an array of oligonucleotides probes comprising the nucleotide sequence of SEQ ID NO:71 or fragments thereof can be constructed to conduct efficient screening of e.g., genetic mutations. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to identify genetic variants, mutations, and polymorphisms. This information may be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents (see for example: Chee, M. et al., Science, 274:610-614 (1996)). It has been shown that multiple classical features of cancer cells can be manifested by improper histone deacetylation [for review see Wade, P.A. Hum Mol Genet;10(7):693-698 (2001)].

Another related embodiment relates to the use of SEQ ID NO:72, its complement, or any part thereof to develop antagonists of the protein of the invention and of the HDAC complex. Antagonists or inhibitors of histone deacetylase may indeed be used to suppress gene silencing. Such antagonists and/or inhibitors may be antibodies specific for the protein of the invention that can be used directly as an antagonist, or indirectly as a targeting or delivery mechanism for bringing a pharmaceutical agent to cells or tissue which express the protein of the invention. Other methods to inhibit the expression of the protein of the invention include antisense and triple helix

strategies as described herein. Other antagonists or inhibitors of the protein of the invention may be produced using methods which are generally known in the art, including the screening of libraries of pharmaceutical agents to identify those which specifically bind the protein of the invention. The protein of the invention, or fragment thereof, preferably its functional or immunogenic fragments, or oligopeptides related thereto, can be used for screening libraries of compounds in any of a variety of drug screening techniques. The fragment employed in such screening may be free in solution, affixed to a solid support, borne on a cell surface, or located intracellularly. The formation of binding complexes, between the protein of the invention, or fragment thereof, or derivative thereof, and the agent being tested, may be measured. Another technique for drug screening which may be used provides for high throughput screening of compounds having suitable binding affinity to the protein of the invention as described in published PCT application WO84/03564. Abnormal gene silencing causes conditions like, but not limited to, accelerated aging syndromes such as Cochayne's syndrome, Ataxia telangiectasia and Werner's syndrome as well as age-associated diseases as well as "early onset" forms of diseases associated with old age such as dementia and Parkinson's disease.

**Protein of SEQ ID:74 (Internal designation Clone 500716683\_204-24-2-0-D12-F)**

The protein of SEQ ID NO:74, herein referred as short Paraplegin, comprising the amino acid sequence:

 20 LQSLQLRLLTPTFEGINGLLLKQHLVQNPVRLWQLLGGTFYFNTSRLKQKNKEKDKSKGK  
 APEEDEGIFI, is encoded by the cDNA of clone 500716683\_204-24-2-0-D12-F (SEQ ID NO:73). Accordingly, it will be appreciated that all characteristics and uses of the polypeptide of SEQ ID NO:74 described throughout the present application also pertain to the polypeptide encoded by a nucleic acid included in clone 500716683\_204-24-2-0-D12-F. In addition, it will be appreciated that all characteristics and uses of the nucleic acid of SEQ ID NO:73 described throughout the present application also pertain to the nucleic acid included in clone 500716683\_204-24-2-0-D12-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:73, SEQ ID NO:74, and Clone 500716683\_204-24-2-0-D12-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:74 is encoded by a nucleic acid of 879 nucleotides with an ORF between nt 9 to 395 yielding a 129 amino acid protein. The protein is a variant of the sequence for human protease and associated protein-15 (PPRG-15) (described in PCT publication WO200009709-A2, the disclosure of which is incorporated herein by reference in its entirety) and of the sequence of the protein associated to hereditary spastic paraplegia (described in PCT publication WO9958556-A2, the disclosure of which is incorporated herein by reference in its entirety). It has a signal peptide spanning 17 amino acid residues at its N-terminal. The protein of

SEQ ID NO:74 is localized in the brain and has a mitochondrial localizing signal peptide.

Moreover, the protein of SEQ ID NO:74 exhibits high homology to the N-terminal of hereditary spastic paraplegia protein sequence (described in PCT publication WO9958556-A2). Hereditary Spastic paraplegia (HSP) is characterized by progressive weakness and spasticity of the lower limbs due to degeneration of corticospinal axons. (Harding, A.E., J. Med. Genet. 18: 436-441(1981); Fink, J.K., et al., Am. J. Hum. Genet. 56:188-192 (1997); Reid, E., J. Med. Genet. 34:499-503, (1997)). This is a genetically heterogeneous group of neurodegenerative disorders affecting approximately 1 in 10,000 individuals (Filla (1992); Polo et al. (1993)). Patients with HSP typically show leg stiffness and gait disturbance, decreased perception of sharp stimulation, and diminished vibratory sense in the distal lower limbs. Both the age of onset and severity of the symptoms are highly variable even among individuals from the same family (Harding, A.E., J. Med. Genet. 18: 436-441(1981); Dürr et al., 1994). Currently, no specific treatment is available to prevent, cure, or delay progression of symptoms of HSP.

In addition to the above-described clinical spectrum, which is typical of the "pure" form of HSP, several patients have been shown to have "complicated" forma of HSP characterized by the presence of additional neurological and non-neurological symptoms such as mental retardation, peripheral neuropathy, amyotrophy, ataxia, retinitis pigmentosa, optic atrophy, deafness, and ichthyosis (Bonneau, D., et al., J. Med. Genet. 30:381-384 (1993); Gigli, G.L., et al., Am. J. Med. Genet. 45:711-716 (1993); Lizcano-Gil, L.A. et al., Am. J. Med. Genet. 68:1-6 (1997); Webb, S., et al., Epilepsia 38:495-499 (1997)). Albeit some of these forms have been found to segregate in families, it is still unclear whether complicated forms of HSP represent distinct genetic entities or variant presentations of pure HSP. However, even in pure forma of HSP (i.e., with clinical features limited to the lower segments), a broader subclinical involvement of the nervous system has been demonstrated [Tedeschi, G. et al., J. Neurol. Sci. 103:55-60 (1991); Dürr, A., et al., Neurology 44:1274-1277 (1994)].

Autosomal dominant, autosomal recessive, and X-linked forms of HSP have been described, indicating genetic heterogeneity [Harding, A.E., J. Med. Genet. 18: 436-441(1981); Fink, J.K., et al., Am. J. Hum. Genet. 56:188-192 (1997); Reid, E., J. Med. Genet. 34:499-503, (1997)]. Casari and collaborators have identified and characterized a gene associated to hereditary spastic paraplegia, located in the telomere region of chromosome 16q, and the protein deriving, therefrom, named paraplegin [Casari, G., et al. Cell 93:973,983 (1998)].

It is believed that the protein of SEQ ID NO:74, or fragment thereof is a mitochondrial protein associated to hereditary spastic paraplegia. The protein of the invention or fragment thereof may play a role in the mitochondrial degradation machinery. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO:74 from positions 1 to 125. Other preferred polypeptides of the invention are fragments of SEQ ID NO:74 having any of the biological activities described herein.

Another embodiment of the invention relates to compositions and methods using the protein of the invention or fragment thereof to label mitochondria in order to visualize any change in number, topology or morphology of this organelle, for example in association with a mitochondria-related human disorder, such as hereditary spastic paraplegia [Casari, G., et al. Cell 5 93:973,983 (1998)], neuroleptic malignant syndrome (NMS) [Kubo et al., Forensic Sci. Int. 115:155-158 (2001)], the Rett syndrome [Armstrong, Brain Dev. 14 Suppl:S89-98 (1992)], Alpers disease [Chow and Thorburn, Hum. Reprod. 15 Suppl 2:68-78 (2000)] or mitochondrial encephalomyopathies [Handran et al., Neurobiol. Dis. 3:287-298 (1997)]. Casari and collaborators have shown that paraplegin protein localizes to mitochondria by immunofluorescence studies 10 [Casari, G., et al. Cell 93:973,983 (1998)]. Paraplegin protein exhibits a helical wheel pattern (an amphiphilic structure composed of basic residues, mainly arginine, on one side and apolar residues on the opposite side) of the N-terminal which is highly homolog to the protein of the invention; moreover the high ratio of arginine to lysin among the first 41 amino acids indicates the presence of typical mitochondrial leader sequences [Casari, G., et al. Cell 93:973,983 (1998)]. For example, 15 the protein may be rendered easily detectable by inserting the cDNA encoding the protein of the invention into a eukaryotic expression vector in frame with a sequence encoding a tag sequence. Eukaryotic cells expressing the tagged protein of the invention may also be used for the *in vitro* screening of drugs or genes capable of treating any mitochondria-related disease or conditions. Another example, the protein of the invention or fragment thereof may be used to generate specific 20 antibodies which would in turn allow the visualization of mitochondrial structures by methods well-known to those of skill in the art.

In another embodiment, the protein of the invention may be used to target heterologous compounds (polypeptides or polynucleotides) to the brain and/or the mitochondria. For instance, a chimeric protein composed of the protein of the invention recombinantly or chemically fused to a 25 protein or polynucleotide of therapeutic interest would allow the delivery of the therapeutic protein/polynucleotide specifically to the above-mentioned cellular/tissue targets (mitochondria, brain). Preferred fragments are the putative peptide signal, and/or any other fragments of the protein of the invention that may contain targeting signals for mitochondria). Such heterologous compounds may be used to modulate mitochondrial activities, such as to induce and/or prevent 30 mitochondrial-induced apoptosis or necrosis. For example, these heterologous compounds may be used in the treatment and/or the prevention of disorders due to mitochondrial dysfunction, including, but not limited to, hereditary spastic paraplegia. In addition, heterologous polynucleotides may be used to deliver nucleic acids for mitochondrial gene therapy, i.e. to replace a defective mitochondrial gene and/or to inhibit the deleterious expression of a mitochondrial gene.

35 An antagonist of the protein of SEQ ID NO:74 may be produced using methods which are generally know in the art. In one aspect, the protein of the invention or fragment may be used to synthesize specific antibodies using any techniques known to those skilled in the art including

those described therein. In particular, purified short paraplegin may be used to produce antibodies or to screen libraries of pharmaceutical agents to identify those which specifically bind short paraplegin.

In a further embodiment, a pharmaceutical composition comprising a substantially purified protein of SEQ ID NO:74 in conjunction with a suitable pharmaceutical carrier may be administered to a subject to treat or prevent a disorder associated with change of expression or activity of short paraplegin including, but not limited to, those described above. The antibody which specifically binds short paraplegin may be used directly as an antagonist or indirectly as a targeting or delivery mechanism for bringing a pharmaceutical agent to cells or tissues which express short paraplegin.

In another embodiment, antibodies which specifically bind the protein of SEQ ID NO: 74 may be used for the diagnosis of disorders characterized by expression of short paraplegin. Truncated forms of paraplegin are involved in hereditary spastic paraplegia (Casari, G., et al. Cell 93:973,983 (1998)). Diagnostics assays for short paraplegin include methods which utilize the antibody and a label to detect short paraplegin in human body fluids or in extract of cells or tissues. A variety of protocols for measuring short paraplegin, including ELISA's, RIAs, and FACs, are known in the art and provide a basis for diagnosing the presence of short paraplegin expression.

In another embodiment, the polynucleotide of SEQ ID NO:73 or a fragment may be used for diagnostic purposes in assays that detect the presence of associated disorders, for example but not limited to, hereditary spastic paraplegia. The polynucleotides which may be used include oligonucleotide sequences, complementary RNA and DNA molecules, PNAs. The polynucleotides may be used to detect and quantitate gene expression in biopsied tissues in which expression of short paraplegin may be correlate with disease. The nucleotide sequences encoding short paraplegin may be labeled by standard methods and added to a fluid or tissue sample from a patient under conditions suitable for the formation of hybridization complexes. After a suitable incubation period, the sample is washed and the signal is quantitated and compared with a standard value. If the amount of signal in the patient sample is significantly increased in comparison to a control sample then the presence of increased levels of nucleotide sequences encoding short paraplegin in the sample indicates the presence of associated disorder, particularly but not limited to, hereditary spastic paraplegia. Such assays may also be used to evaluate the efficacy of a particular therapeutic treatment regimen in animal studies, in clinical trials, or to monitor the treatment of an individual patient.

Once the presence of a disorder is established and a treatment protocol is initiated, hybridization assays may be repeated on a regular basis to determine if the level of expression in the patient begins to approximate that which is observed in the normal subject. The results obtained from successive assays may be used to show the efficacy of treatment over a period of time.

In another embodiment, an array of oligonucleotides probes comprising the nucleotide sequence of SEQ ID NO:73 or fragments thereof can be constructed to conduct efficient screening of e.g., genetic mutations. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to identify genetic variants, mutations, and polymorphisms.

- 5 This information may be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents [see for example: Chee, M. et al., Science, 274:610-614 (1996)]. For example, it has been shown that genetic variants, mutations, and polymorphisms are related to hereditary spastic paraplegia [for review see Casari, G., and Rugarli, E. Curr. Opin. Genetics and Development, 11:336-342  
10 (2001)].

- In another preferred embodiment, the protein of the invention or fragment thereof can be used in an enzyme/prodrug strategy to treat a number of pathologies, especially those treated with drugs associated with severe side effects, including, but not limited to, autoimmune diseases and chronic inflammatory diseases such as rheumatoid arthritis, and cancer chemotherapy. These side  
15 effects can be mainly explained by the fact that the in vivo selectivity of the drugs used is too low (for example, the inadequate selectivity between tumor and normal cells of most anticancer drugs is well known and their toxicity to normal tissues is dose limiting). In the first phase of one example of such a protocol, a conjugate of the protein of the invention or fragment thereof and an antibody to a tissue specific antigen (for example, tumor specific antigens in the case of cancer  
20 chemotherapy) is administered. After a delay to allow residual enzyme conjugate to be cleared from the blood, a relatively non-toxic compound is administered to the patient. This non-toxic compound is a substrate of the protein of the invention, and is converted by the protein into a substantially more toxic compound. Thus, because of the previous, targeted administration of the protein of the invention, when the non-toxic compound is administered, the toxic compound is  
25 only produced in the vicinity of the cells targeted by the fusion protein. This two-phase approach has been termed antibody-directed enzyme-prodrug therapy (ADEPT), this approach is reviewed by Melton et al. [Melton R. et al., J. Natl. Cancer Inst., 88, p153-165 (1996)]. Alternatively the first phase can be replaced by a gene therapy approach resulting in the de novo synthesis of the protein of the invention or fragment thereof by cells from the targeted tissue, this has been termed  
30 gene-dependent enzyme/prodrug therapy (GDEPT). Another advantage of these 2 approaches (ADEPT and GDEPT) is that a single enzyme molecule is capable of activating many prodrug molecules.

**Protein of SEQ ID:76 (Internal designation Clone 500760207\_205-58-4-0-H6-F)**

- The protein of SEQ ID NO:76, herein referred as Ketothiolase (KT), comprising the amino  
35 acid sequence:

MMGVFVVAAKRTPFGAYGGLLKDFTATDLSEFAAKAALSAGKVSPETVDSVIMGNVLQS  
SSDAIYLARHVGLRVGIPKETPALTINRLCGSGFQSIVNGCQEICVKEAEVVLCGGTESMSQ

 ALKKAGLSLKDMDLVEVNEAFAPQYLAVERSLDLDISKTNVNGGAIALGHPLGGSGSRIT

5 AHLVHELRRRGKYAVGSACIGGGQGIAVIIQSTA, is encoded by the cDNA of clone  
 500760207\_205-58-4-0-H6-F (SEQ ID NO:75). Accordingly, it will be appreciated that all  
 characteristics and uses of the polypeptide of SEQ ID NO:76 described throughout the present  
 application also pertain to the polypeptide encoded by the human cDNA of clone 500760207\_205-  
 58-4-0-H6-F. In addition, it will be appreciated that all characteristics and uses of the nucleic acid  
 10 of SEQ ID NO:75 described throughout the present application also pertain to the human cDNA of  
 clone 500760207\_205-58-4-0-H6-F. A preferred embodiment of the invention is directed toward  
 the compositions of SEQ ID NO:75, SEQ ID NO:76, and Clone 500760207\_205-58-4-0-H6-F.  
 Also preferred are polypeptide fragments having a biological activity as described herein and the  
 polynucleotides encoding the fragments.

15 The protein of SEQ ID NO:76 encoded by the cDNA of SEQ ID NO:75 is a polymorphism  
 variant of 3-Ketoacyl CoA Thiolase protein (GENPEPT accession number D16294).  
 Furthermore, a BLAST search with the amino acid sequence of SEQ ID NO:76 indicates that the  
 protein of the invention is homologous to 3-Ketoacyl CoA thiolase of rat (Swissprot accession  
 number P13437) and *Bacillus halodurans* (Genbank accession number AP001514).

20 The 394 amino acids protein of SEQ ID NO:76 displays 1 candidate membrane-spanning  
 segment, from amino acids 373 to 393. Accordingly, some embodiments of the present invention  
 relate to polypeptides comprising the transmembrane domain. Finally, the protein of the invention  
 displays the 3 thiolase signatures (PS00098, PS00737, PS00099) spanning from positions 85 to  
 103, positions 339 to 355, and positions 374 to 387, respectively. Accordingly, some embodiments  
 25 of the present invention relate to polypeptides comprising the thiolase signature.

Living organisms are exposed to a number of different fatty acids and their various  
 derivatives arising either via endogenous synthesis or from exogenous sources. These hydrophobic  
 compounds can play specific metabolic, structural or endocrinic functions in the organisms before  
 their elimination, which can be metabolism to CO<sub>2</sub> or to more polar lipid metabolites allowing  
 30 their excretion. Quantitatively, one of the major pathways metabolizing fatty acids is  $\beta$ -oxidation,  
 which is often described as a spiral of four reactions catalyzed by three enzymes.

The three consecutive steps of mitochondrial  $\beta$ -oxidation of fatty acids, including the long-  
 chain 3-hydroxyl-CoA dehydrogenase, are catalyzed by the trifunctional protein: 2-enoyl-CoA  
 hydratase, 3-hydroxyacyl-CoA deshydrogenase and 3-ketoacyl-CoA thiolase. Deficiencies in  
 35 enzyme activities of the heterocomplex, which contains 4 alpha and 4 beta subunits, causes sudden  
 unexplained infant death, a Reye-like syndrome, cardiomyopathy, or skeletal myopathy.

Defects in the trifunctional protein fall into two groups: patients with an isolated defect in

3-hydroxyacyl-CoA dehydrogenase and those with a deficiency in all three activities and absence of immunoreactive protein (Tyni, J. et al., Acta Paediatr. 88:237-245 (1999)). Patients in the second group have been found to have either deletions in the  $\alpha$ -subunit cDNA encoding for 2-enoyl-CoA hydratase and 3-hydroxyacyl-CoA deshydrogenase or point mutations in the  $\beta$ -subunit encoding for 3-ketoacyl-CoA thiolase [Ushikubo, S. et al., Am. J. Hum. Genet. 58: 979-988 (1996); Ori, K.F. et al., Hum. Mol Genet. 6: 1215-1224 (1997)].

It is believed that the protein of SEQ ID NO: 76 or fragment thereof is an hydrolase, preferably acting on ester bonds, more preferably a thiolester hydrolase, even more preferably an ketoacyl-CoA thiolase which, as such, plays a role in fatty acid metabolism, in cellular vesicle transport and maintenance of the cytoarchitecture, in cellular proteolysis, endocytosis, signal transduction, lysosomal storage, cell proliferation and differentiation, immune and inflammatory response. The enzyme's substrates are compounds preferably containing an ester bond, preferably a thiol ester bond, more preferably an acyl thioester bond. Preferred polypeptides of the invention are polypeptides comprising the amino acids of SEQ ID NO: 76 from positions 85 to 103, positions 15 339 to 355, and positions 374 to 387. Other preferred polypeptides of the invention are fragments of SEQ ID NO: 76 having any of the biological activities described herein. The hydrolytic activity of the protein of the invention or fragment thereof may be assayed using any of the assays known to those skilled in the art including those described in US patents 5,445,942. The ability to bind a cofactor may also be assayed using any techniques well known to those skilled in the art including, 20 for example, the assay for binding NAD described in US patent 5,986,172.

Another embodiment of the invention relates to compositions and methods using the protein of the invention or fragment thereof to label mitochondria, or more specifically the inner mitochondrial membrane, in order to visualize any change in number, topology or morphology of this organelle, for example in association with a mitochondria-related human disorder, such as 25 neuroleptic malignant syndrome (NMS) (Kubo et al., Forensic Sci. Int. 115:155-158 (2001)), the Rett syndrome (Armstrong, Brain Dev. 14 Suppl:S89-98 (1992)), Alpers disease (Chow and Thorburn, Hum. Reprod. 15 Suppl 2:68-78 (2000)) or mitochondrial encephalomyopathies (Handran et al., Neurobiol. Dis. 3:287-298 (1997)). For example, the protein may be rendered easily detectable by inserting the cDNA encoding the protein of the invention into a eukaryotic 30 expression vector in frame with a sequence encoding a tag sequence. Eukaryotic cells expressing the tagged protein of the invention may also be used for the *in vitro* screening of drugs or genes capable of treating any mitochondria-related disease or conditions.

In one embodiment, the invention relates to compositions and methods using the protein of SEQ ID NO: 76 or fragment thereof as a marker for tissue types (especially placenta), or to 35 distinguish between two or more possible sources of a tissue sample on the basis of the level of the protein of SEQ ID NO:76 in the sample. For example, the protein of SEQ ID NO:76 or fragments thereof may be used to generate antibodies using any techniques known to those skilled in the art,

and the antibodies may then be used to identify tissues of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using immunochemistry. Typically, in such methods a tissue sample is contacted with the antibody, which may be detectably labeled, under conditions which facilitate antibody binding. In one embodiment, the level of antibody binding to the test sample is measured and compared to the level of binding expected from control cells from placenta, or tissues other than placenta to determine whether the test sample is from placenta. Such methods may also be performed in conjunction with other, independent methods for determining cellular identity. Similar methods can be used to specifically detect cells expressing the protein, as well as to specifically isolate cells expressing the protein or to isolate the protein itself. For example, an antibody against the protein of SEQ ID NO:76 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing cells expressing the protein of SEQ ID NO:76 is placed in contact with the antibody under conditions which facilitate binding to the antibody. The support is washed and then the protein is released from the support by contacting the support with agents which cause the protein to dissociate from the antibody.

In another embodiment, the protein of the invention may be used to target heterologous compounds (polypeptides or polynucleotides) to the placenta and/or the cell mitochondria. For instance, a chimeric protein composed of the protein of the invention recombinantly or chemically fused to a protein or polynucleotide of therapeutic interest would allow the delivery of the therapeutic protein/polynucleotide specifically to the above-mentioned cellular/tissue targets (mitochondria, placenta).

Another embodiment of the invention relates to composition and methods using polynucleotide sequences encoding the protein of the invention or fragment thereof to establish transgenic model animals (*D. melanogaster*, *M. musculus*), by any method familiar to those skilled in the art. By modulating *in vivo* the expression of the transgene with drugs or modifier genes (activator or suppressor genes), animal models can be developed that mimic human mitochondria-associated disorders such as myopathies or obesity. These animal models would thus allow the identification of potential therapeutic agents for treatment of the disorders. In addition, recombinant cell lines derived from these transgenic animals may be used for similar approaches *ex vivo*.

In another embodiment, the invention relates to compositions and methods using the proteins of the invention or fragment thereof such as ligands for substrates of interest. In a preferred embodiment, the proteins of the invention or fragment thereof may be used to identify and/or quantify substrates using any techniques known to those skilled in the art. To find substrates, the proteins of the invention, or fragment thereof, or derivative thereof, may be used for screening libraries of compounds in any of a variety of drug screening techniques. The fragment

employed in such screening may be free in solution, affixed to a solid support, borne on a cell surface, or located intracellularly. The formation of binding complexes, between the proteins of the invention, or fragment thereof, or derivative thereof, and the agent being tested, may be measured. Antagonists or inhibitors of the proteins of the invention may be produced using

- 5 methods which are generally known in the art, including the screening of libraries of pharmaceutical agents to identify those which specifically bind the protein of the invention. Another technique for drug screening which may be used provides for high throughput screening of compounds having suitable binding affinity to the proteins of the invention as described in published PCT application WO84/03564.

- 10 In another embodiment, the invention relates to methods and compositions for detecting and quantifying the level of the protein of the invention present in a particular biological sample. These methods are useful for the diagnosis or prognosis of diseases associated with an altered levels of the protein of the invention like, but not limited to, deficiency of the hydrogenase activity (LCHAD deficiency). Diagnostic assays to detect the protein of the invention may comprise a
- 15 biopsy, in situ assay of cells from organ or tissue sections, or an aspirate of cells from a tumor or normal tissue. In addition, assays may be conducted upon cellular extracts from organs, tissues, cells, urine, or serum or blood or any other body fluid or extract.

- Assays for the quantification of the KT of SEQ ID NO:76 may be performed according to methods well known in the art. Typically, these assays comprise contacting the sample with a
- 20 ligand of the protein of the invention or an antibody (polyclonal or monoclonal) which recognizes the protein of the invention or a fragment thereof, and detecting the complex formed between the protein of the invention present in the sample and the ligand or antibody. Fragments of the ligands and antibodies may also be used in the binding assays, provided these fragments are capable of specifically interacting with the KT of the subject invention. Further, the ligands and antibodies
- 25 which bind to the KT of the invention may be labeled according to methods known in the art. Labels which are useful in the subject invention include, but are not limited to, enzymes labels, radioisotopic labels, paramagnetic labels, and chemiluminescent labels. Typical techniques are described by Kennedy, J. H., *et al.* (1976) *Clin. Chim. Acta* 70:1-31; and Schurs, A. H. *et al.* (1977) *Clin. Chim. Acta* 81: 1-40.

- 30 In another embodiment, the present invention includes the use of the protein of SEQ ID NO:76, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. For example, the condition may be deficiency of the hydrogenase activity (LCHAD deficiency), hypoglycemia, muscular hypotonia, hyperamonia, mild liver dysfunction, 3-hydroxydicarboxylic aciduria, cardiomyopathy, retinal dystrophy, Bannayan-Riley-Ruvalcaba
- 35 syndrome, or an abnormality in any of the functions of the hydrogenase activity. In such embodiments, the protein of SEQ ID NO:76, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of the protein of SEQ ID NO:76.

The protein of SEQ ID NO:76 or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding the protein of SEQ ID NO:76 or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of the protein of SEQ ID NO:76 may be administered to the individual. Such agents may be identified by

- 5 contacting the protein of SEQ ID NO:76 or a cell or preparation containing the protein of SEQ ID NO:76 with a test agent and assaying whether the test agent increases the activity of the protein.

For example, the test agent may be a chemical compound or a polypeptide or peptide.

- Alternatively, the activity of the protein of SEQ ID NO:76 may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity  
10 of the protein of SEQ ID NO:76 may be identified by contacting the protein of SEQ ID NO:76 or a cell or preparation containing the protein of SEQ ID NO:76 with a test agent and assaying whether the test agent decreases the activity of the protein. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid.

- 15 In another embodiment, the invention also relates to the use of polynucleotides of SEQ ID NO:75 as diagnostic reagents. Detection of a mutated form of the gene characterized by the polynucleotide of SEQ ID NO:75 which is associated with a dysfunction will provide a diagnostic tool that can add to, or define, a diagnosis of a disease, or susceptibility to a disease. It has been shown previously that mutations in the beta subunit are responsible for trifunctional protein related  
20 diseases like those listed above [Ushikibo, S., et al., Am. J. Hum. Genet. 58:979-988 (1996); Ori, K.F. et al., Hum. Mol Genet. 6:1215-1224 (1997)]. Individuals carrying mutations in the gene may be detected at the DNA level by a variety of techniques known by those skilled in the art. Nucleic acids for diagnosis may be obtained from a subject cells, such as from blood, urine, saliva, tissue biopsy or autopsy material. The genomic DNA may be used directly for detection or may be  
25 amplified enzymatically by using PCR or other amplification techniques prior to analysis.

In another embodiment, an array of oligonucleotides probes comprising the nucleotide sequence of SEQ ID NO:75 or fragments thereof can be constructed to conduct efficient screening of e.g., genetic mutations. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to identify genetic variants, mutations, and polymorphisms.

- 30 This information may be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents (see for example: Chee, M. et al., Science, 274:610-614 (1996)).

**Protein of SEQ ID NO:78 (Internal designation Clone 122421\_105-076-4-0-H1-F)**

- The cDNA of clone 122421\_105-076-4-0-H1-F (SEQ ID NO:77) encodes the protein of  
35 SEQ ID NO:78, comprising the amino acid sequence:

MAAALFVLLGFALLGTHGASGAAGTVFTTVEDLGSKILLTCSLNDSEVTGHRWLKGG  
VVLKEDALPGQKTEFKVDSDDQWGEYSCVFLPEPMGTANIQLHGPPRVKAVKSSEHINEG

ETAMLVCKSESVPVTDWAWYKITDSEDKALMNGSESRRFFVSSSQGLSELHIENLNMEAD  
PGQYRCNGTSSKGSQAIITLRVRSHLAALWPFLGIVAEVLVLVTIIFIYEKRRKPEDVLDD  
DDAGSAPLKSSGQHQNKGKGNVRQRNSS. Accordingly, it will be appreciated that all

characteristics and uses of the polypeptide of SEQ ID NO:78 described throughout the present  
5 application also pertain to the polypeptide encoded by the nucleic acids included in clone  
122421\_105-076-4-0-H1-F. In addition, it will be appreciated that all characteristics and uses of  
the nucleic acid of SEQ ID NO:77 described throughout the present application also pertain to the  
nucleic acids included in clone 122421\_105-076-4-0-H1-F. A preferred embodiment of the  
invention is directed toward the compositions of SEQ ID NO:77, SEQ ID NO:78, and Clone  
10 122421\_105-076-4-0-H1-F. Also preferred are polypeptide fragments having a biological activity  
as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:78 (BAS12) is a novel polymorphic variant of human basigin.  
BAS12 displays a signal peptide (MAAALFVLLGFALLGTHG), and two immunoglobulin (Ig)  
domains

15 (GSKILLTCSLNSATEVTGHRWLKGGVVLKEDALPGQKTEFKVDSDDQWGEYSCVF and  
GETAMLVCKSESVPVTDWAWYKITDSEDKALMNGSESRRFFVSSSQGLSELHIENLNMEA  
DGQYRCNGTSS). Furthermore, BAS12 displays three N-glycosylation sites (NDSA, NGSE, and  
NGTS). The arginine at position 166 in basigin is changed to leucine in BAS12. Thus, the  
polymorphic, nonconservative change present in BAS12 is located in the second Ig domain, which  
20 is involved in protein-protein interactions. Such a polymorphic change located in the second Ig  
domain has never been previously reported. Thus, as a novel polymorphic variant of basigin,  
BAS12 displays similar biological activities as basigin, but displays enhanced kinetic parameters  
during protein-protein interactions.

BAS12 is a member of the immunoglobulin superfamily, which includes T cell receptors,  
25 neural cell adhesion molecules and major histocompatibility complex antigens. BAS12 is a cell  
surface transmembrane glycoprotein that is broadly distributed, and expressed at particularly high  
levels on activated gliomas, on tumor cells, on activated T cells and at the retinal pigment  
epithelium and neonatal blood-brain barrier. BAS12 is involved in cell-cell interactions, and has a  
multiplicity of biological roles. Notably, BAS12 stimulates the biosynthesis of various matrix  
30 metalloproteinases (MMPs), a group of enzymes involved in the degradation of most of the  
components of the extracellular matrix. In particular, MMP biosynthesis is crucial in tumor  
secretion and in immune response. BAS12 plays a role in spermatogenesis and fertilization, in  
neuronal interactions in the central nervous system and in HIV-1 infection.

An embodiment of the present invention relates to methods of using BAS12 or fragment  
35 thereof to stimulate the biosynthesis of metalloproteinases. In a preferred embodiment,  
metalloproteinases produced by such methods can be used in a "cocktail" of proteases that is able  
to digest a wide range of proteins without knowing any of the proteins. Such protease cocktails are

useful in laboratory assays to degrade undesirable proteins in a sample, for example for removing proteins in a DNA preparation or for removing enzymes after any enzymatic reaction. In another preferred embodiment, metalloproteinases produced by such methods can be used for screening and/or assaying metalloproteinase inhibitors. Such metalloproteinase inhibitors are very useful to  
5 treat and/or prevent a wide range of diseases associated to metalloproteinase activation. In still another preferred embodiment, metalloproteinases produced by such methods can be used for degradation of connective tissues, for example in food industry. Any method of stimulating metalloproteinases biosynthesis can be used in such methods. For example, fibroblasts can be stimulated as described by Guo *et al* (J Biol Chem 272:24-7 (1997 )), which disclosure is hereby  
10 incorporated by reference in its entirety.

An embodiment of the present invention relates to methods of using BASI2 or fragment thereof for the diagnosis of cancers, graft rejections, and graft versus host diseases. In such methods, BASI2 or fragment thereof is used as a marker to detect and/or quantify cells in which BASI2 and/or basigin expression is up-regulated, and in which MMPs are synthesized. Any  
15 method of detecting the presence, level or activity of BASI2 and/or basigin can be used in such methods. For example, the protein of the invention or fragment thereof may be used to generate specific antibodies using standard methods. Preferably, the antibodies are either directly or indirectly labeled, and recognize the second Ig domain. In a preferred embodiment, the antibodies bind more specifically to BASI2 than to related proteins such as basigin. Such antibodies can be  
20 used for specifically detecting the presence of the BASI2 variant. In another preferred embodiment, the antibodies recognize both basigin and BASI2. Such antibodies can be used for detecting total amount of basigin and BASI2 molecules. Alternatively, the nucleic acid of the invention or fragment thereof may be used to synthesize specific probes using any technique known to those skilled in the art. In such assays and diagnostic kits, the detection of a higher level  
25 of BASI2 and/or basigin expression, compared to a control representative of a non-malignant cell coming from a given tissue or bodily fluid, diagnostics the presence of a tumor or the beginning of a graft rejection reaction.

Another embodiment of the present invention relates to compositions and methods for inhibiting the activity or expression of BASI2 in a patient for the treatment or prevention of  
30 disorders caused or aggravated as a result of metalloproteinase biosynthesis. The inhibition of BASI2 activity or expression can be achieved using any suitable method, e.g. through administration of a therapeutically effective amount of an antibody that recognizes BASI2 or fragment thereof to a patient. Preferably, the antibodies are either directly or indirectly labeled, and recognize the second Ig domain. In a preferred embodiment, the antibodies bind more  
35 specifically to BASI2 than to related proteins such as basigin. Such antibodies can be used for specifically inhibiting the BASI2 variant. In another preferred embodiment, the antibody recognizes both BASI2 and basigin. Such antibodies can be used for inhibiting both isoforms.

The antibody can be administrated alone or in combination with one or more agent known in the art, e.g. ABX-CBL antibody described in PCT Patent WO99/45031. Administration of the antibody can be done following any method known in the art, including that described in PCT Patent WO99/45031, which disclosure is hereby incorporated by reference in its entirety. Other inhibitors of BASI2 expression or activity which can be used include, but are not limited to, antisense molecules, ribozymes, dominant negative forms of BASI2, and compounds that decrease the activity or expression of BASI2 in a cell. Such compounds can be readily identified, e.g. by screening test agents tumor cells overexpressing BASI2, and detecting the ability of the test agents to decrease metalloproteinase biosynthesis or to diminish the level of BASI2 expression. Diseases and disorders caused or aggravated as a result of MMP biosynthesis and that can be treated by administering an inhibitor of BASI2 and/or basigin include but are limited to cancers, graft rejections and graft versus host diseases.

Still another embodiment relates to compositions and methods for inhibiting the expression or activity of BASI2 in a patient for the treatment or prevention of disorders caused or aggravated as a result of microglial activation. The inhibition of BASI2 activity or expression can be achieved using any of the methods described above. Disorders caused or aggravated as a result of microglial activation include but are not limited to spinal cord contusion, Huntington disease, dementia with Lewy bodies, ischemia, multiple sclerosis, and Alzheimer's disease.

Still another embodiment relates to compositions and methods for inhibiting the interaction between BASI2 and cyclophilin A (CyPA) in a patient, in order to treat or to reduce in severity HIV-infection. Inhibition of the interaction can be achieved using any suitable method, e.g. through administration of a therapeutically effective amount of an antibody that recognizes BASI2 or fragment thereof to a patient. Preferably, the antibodies are either directly or indirectly labeled, and recognize the first Ig domain and/or the second Ig domain. Administration of the antibodies can be performed as described above.

Another embodiment of the present invention relates to compositions and methods for enhancing the expression or activity of BASI2 and/or basigin in a patient for the treatment or prevention of disorders caused or aggravated as a result of BASI2 and/or basigin deficiency such as sterility, learning and memory impairments, and retinal angiogenesis. Any method or composition enhancing the expression or activity of BASI2 and/or basigin, containing BASI2 or fragment thereof, a polynucleotide encoding the protein, or a compound that increases the expression or activity of BASI2, can be used. Such compounds can be readily identified, e.g. by screening test agents against non activated glial cells expressing BASI2 and detecting the ability of the test agents to enhance metalloproteinases biosynthesis, or to increase the level of BASI2 expression. The compositions of the invention can be administered directly to the patient using any suitable method, for example by intravenous perfusion or by oral administration. Effective doses of the polypeptides of the present invention are determined according to the relevant techniques.

**Protein of SEQ ID NO:80 (Internal designation 99483\_105-016-1-0-D7-F)**

The cDNA clone 99483\_105-016-1-0-D7-F (SEQ ID NO:79) encodes KSPI1, the protein of SEQ ID NO:80, comprising the amino acid sequence:

MLPPRPAAALALPVLLLLLVLTTPPTGARSPGPDYLRRGWMRLLAEGEGCAPCRPEEC  
 5 AAPRGCLAGRVRDACGCCWECANLEGQLCDLDPSAHFYGHCGEQLECRDGTGGDL SRG  
 EVPEPLCACRSQSPLCGSDGHTYSQICRLQEAARARPDANLTVAHGPGCESGPQIVSHPYD  
 TWNV TGQDVIFGCEVFAYPMASIEWRKDGLDIQLPGDDPHISVQFRGGPQRFEVTGWLQI  
 QAVRPSDEGTYRCLGMPWVKWRPLLA. Accordingly, it will be appreciated that all  
 characteristics and uses of the polypeptide of SEQ ID NO:80 described throughout the present  
 10 application also pertain to the polypeptide encoded by the nucleic acids included in clone  
 99483\_105-016-1-0-D7-F. In addition, it will be appreciated that all characteristics and uses of the  
 nucleic acid of SEQ ID NO:79 described throughout the present application also pertain to the  
 nucleic acids included in clone 99483\_105-016-1-0-D7-F. A preferred embodiment of the  
 invention is directed toward the compositions of SEQ ID NO:79, SEQ ID NO:80, and Clone  
 15 99483\_105-016-1-0-D7-F. Also preferred are polypeptide fragments having a biological activity  
 as described herein and the polynucleotides encoding the fragments. Preferred KSPI1 polypeptides  
 for uses in the methods described below include the polypeptides comprising the amino sequence  
 of:

CAPCRPEECAAPRGCLAGRVRDACGCCWECANLEGQLCDLDPSAHFYGHCGEQL  
 20 ECRDGTGGDL SRGEVPEPLCACRSQSPLCGSDGHTYSQICRLQEAARARPDANLTVAHGPG  
 C and the polypeptide comprising the amino acid sequence of:  
 VPEPLCACRSQSPLCGSDGHTYSQICRLQEAARARPDANLTVAHGPGC.

The protein of SEQ ID NO:80 (KSPI1) is a 267-amino-acid long protein, and is a new  
 variant of the bA108L7.1 gene (Genbank accession number AL133215). The 255 first amino-  
 25 acids are identical between the two proteins, but the 12 last amino-acids of KSPI1 are unique.  
 KSPI1 displays a signal peptide (MLPPRPAAALALPVLLLLLVLTTPPTGA), a kazal-type  
 serine protease inhibitor (Ki) domain  
 (VPEPLCACRSQSPLCGSDGHTYSQICRLQEAARARPDANLTVAHGPGC), an  
 Immunoglobulin-like (Ig) domain  
 30 (QDVIFGCEVFAYPMASIEWRKDGLDIQLPGDDPHISVQFRGGPQRFEVTGWLQIQAVRPS  
 DEGTYRCLG) and an Insulin-like growth factor-binding domain  
 (CAPCRPEECAAPRGCLAGRVRDACGCCWECANLEGQLC). Furthermore, KSPI1 displays  
 homologies with many Insulin-like growth factor-binding proteins (IGFBP) from positions 1 to  
 255, and highest homology with a well-known IGFBP is obtained with human MAC25.  
 35 KSPI1 is a new Kazal-type serine protease inhibitor. Protease inhibitors are important  
 tools of nature for regulating the proteolytic activity of their target proteases, for blocking these in  
 emergency cases, or for signaling receptor interaction or clearance. Kazal-type serine proteases

inhibitors have been shown to inhibit a number of serine proteases such as trypsin, elastase, acrosin, and thrombin. As these proteases are involved in major biological processes such as haemostasis, inflammation and apoptosis, their inhibitors may have a wide range of therapeutical applications (Dahlback, *Lancet*, 355:1627-32 (2000); Watorek et al., *Adv Exp Med Biol*, 240:23-31 (1988); Martin et al, *Cell*, 82:349-52 (1995)).

Moreover, KSPI1 belongs to the low affinity IGFBP family. IGFBPs are soluble proteins that bind insulin-like growth factors (IGFs). IGFs are involved in the regulation of cellular growth and metabolism, and the principal function of IGFBPs is to regulate IGF availability in body fluids. Some serine protease inhibitors have been shown to be implicated in the activation of growth factors (Kawaguchi *et al*, *J Biol Chem* 272:27558-64 (1997)). As KSPI1 is a serine protease that belongs to the low affinity IGFBP family, KSP1 binds to IGFs and modulates IGF activation by inhibiting a serine protease.

An embodiment of the present invention relates to methods of using KSPI1 or fragment thereof to inhibit contaminating proteases in a sample. In particular, KSPI1 can be used in a "cocktail" of protease inhibitors that is able to inhibit a wide range of proteases without knowing the specificity of any of the proteases. Such protease inhibitor cocktails are widely used in laboratory assays to prevent degradation of protein samples by contaminating proteases.

In another embodiment, KSPI1 or fragment thereof can be used to treat and/or attenuate thrombin-mediated and thrombin-associated diseases. Thrombin is a serine protease that regulates the last step in the coagulation cascade, and has a central regulatory role in haemostasis and thrombus formation. Any compositions and methods containing, e.g., KSPI1 or fragment thereof, a polynucleotide encoding the protein, or a compound that increases the expression or activity of KSPI1. Such compounds can be readily identified, e.g. by screening test agents against cells expressing KSPI1 and detecting the ability of the test agents to increase the level of KSPI1 expression. A method for determining the ability of the polypeptides of the invention to block the proteolytic activity of thrombin is described in U. S. Patent 6,218,365. The compositions of the invention can be administered directly to the patient using any suitable method, for example by intravenous perfusion or by oral administration. The compositions of the invention can also be used in extracorporeal circuits, as necessary in dialysis and surgery. Effective doses of the polypeptides of the present invention are determined according to the relevant techniques. The compositions of the invention may be administered alone or in combination with other known agents inhibiting proteases of the coagulation cascade. Thrombin-mediated and thrombin-associated diseases in which the coagulation cascade is activated include but are not limited to deep vein thrombosis, pulmonary embolism, thrombophlebitis, arterial occlusion from thrombosis or embolism, arterial reocclusion during or after angioplasty or thrombolysis, restenosis following arterial injury or invasive cardiological procedures, postoperative venous thrombosis or embolism, acute or chronic atherosclerosis, stroke, myocardial infarction.

In another preferred embodiment, KSPI1 or fragment thereof can be used to treat and/or attenuate diseases associated with neutrophil-released proteases. Activated neutrophils release serine proteases such as elastase or cathepsin G, which result in abnormal connective tissue turnover and in severe damage to healthy tissues if not properly controlled [Watorek et al., Adv Exp Med Biol, 240:23-31 (1988)]. KSPI1 or fragment thereof inhibit neutrophil-released proteases, and inhibition efficiency of the polypeptides of the invention can be determined by measuring *in vitro* the apparent equilibrium dissociation constants using methods derived for tight-binding inhibitors [Bieth, Proteinase Inhibitors. 463-9 (1974); Williams et al, Methods Enzymol. 63:437-67 (1979)]. The compositions of the invention can be administered directly to the patient using any suitable method, for example by intravenous perfusion or by oral administration. Effective doses of the polypeptides of the present invention are determined according to the relevant techniques. The compositions of the invention may be administered alone or in combination with other known agents inhibiting neutrophil-released proteases. Diseases caused by neutrophil-released proteases include but are not limited to emphysema, idiopathic pulmonary fibrosis, adult respiratory distress syndrome, cystic fibrosis, rheumatoid arthritis, organ failure, glomerulonephritis and various inflammatory diseases.

Another embodiment of the invention relates to the inhibition and/or attenuation of proteases produced by pathogenic microorganisms. This embodiment relates to the administration of KSPI1 or fragment thereof, or a compound that increases the expression or activity of KSPI1, alone or in combination with other known agents, for preventing and/or treating parasitic infections in human, in animals and in cell cultures. It has previously been shown that protease inhibitors can prevent dissemination of a virus, a protozoa, a bacteria or a fungus in the host organism. Methods for determining the ability of the polypeptides of the invention to block the proteolytic activity of serine proteases from various pathogenic microorganisms, for preparing and evaluating the pharmaceutical compositions, and for administering the compositions are described in U. S. Patent 5,739,283, which disclosure is hereby incorporated in its entirety. Accordingly, the polypeptides of the present invention may be used to prevent or to treat, e.g., coccidiosis, staphylococcal infection, infection by the influenza virus, *P. gingivalis* or *T. denticola*, and invasive pulmonary aspergillosis.

Another embodiment of the present invention relates to methods of using KSPI1 or fragment thereof to remove or to purify serine proteases in a sample. Such methods can be useful either for removing contaminating proteases from a sample or for purifying a given protease in a sample. Preferred polypeptides are KSPI1 in its entirety, polypeptides containing the Ki domain, and polypeptides containing the Ki and the Ig domains. Recombinant proteins that display the Ki and/or Ig of KSPI1 may also be used. The binding efficacy of KSPI1 to a given serine protease can be tested using any suitable method, e.g., immunoprecipitation and Western blots analysis. Any method of binding KSPI1 to the protease and of purifying the complex can be used in such

methods. In a preferred embodiment, KSPI1 or fragment thereof may be bound to a chromatographic support, either alone or in combination with other proteases inhibitors, to form an affinity chromatography column. The sample to analyse could then be run through this affinity chromatography column.

- 5 Another embodiment of the present invention relates to methods of using KSPI1 or fragment thereof to detect and/or to quantify the amount of protease in a sample, and thus to use these methods in assays and diagnostic kits for the quantification of proteases in samples, bodily fluids or cell cultures. Such assays can be used to calculate the yield of a serine protease purification, and such diagnosis kits, which also contain a sample representative of the amount of
- 10 protease found in a normal subject, can be used to detect diseases and disorders caused as a result of protease activity, including those listed above. Preferred polypeptides are KSPI1 in its entirety, polypeptides containing the Ki domain, and polypeptides containing the Ki and the Ig domains. Any method of detecting the protease inhibitor activity of KSPI1 or fragment thereof can be used in such methods. For example, the sample is assayed using a standard protease substrate. A
- 15 known concentration of KSPI1 or fragment thereof is added, and allowed to bind to a particular protease present. The protease assay is then rerun, and the loss of activity is then correlated to the protease inhibitor activity using techniques well-known to those skilled in the art.

- Still another embodiment of the invention relates to compositions and methods for modulating IGF activity by decreasing binding of KSPI1 to IGFs. Compounds that inhibit the
- 20 interaction of an IGF with any one of its binding proteins and not to a human IGF receptor are useful to increase serum and tissue levels of active IGFs in a mammal. Thus, compositions and methods for decreasing binding of KSPI1 to IGFs can be used, for example, in any treatments where IGFs are usually administrated, e.g., treatment of hyperglycemic, obesity-related, neurological, cardiac, renal, immunologic, and anabolic disorders. The inhibition and/or reduction
- 25 of binding of KSPI1 to IGFs can be achieved using any suitable method, e.g. through the administration of a therapeutically effective amount of an antibody that specifically recognizes KSPI1 or fragment thereof to a patient. Preferably, two antibodies are used, separately or simultaneously, one recognizing the Ig domain and the other recognizing the Ki domain. The antibody can be administered alone or in combination with one or more agent known in the art, e.g.
- 30 those described in U.S. Patent 6,251,865, which disclosure is hereby incorporated by reference in its entirety. Effective doses of the antibodies of the present invention are determined according to the relevant techniques. Decreased binding of KSPI1 to IGFs can also be obtained by using methods and compounds decreasing KSPI1 expression or activity. Such methods and compounds include, but are not limited to, antisense molecules, ribozymes, dominant negative forms of KSPI1,
- 35 and compounds that decrease the activity or expression of KSPI1 in a cell.

Another embodiment of the present invention relates to methods of using KSPI1 or fragment thereof to purify IGFs in a sample. Such methods of purifying IGFs can be used to

analyse the different IGFs present in a patient suffering of one of the diseases listed above. The binding efficacy of KSPI1 to a given IGF can be tested using any suitable method, e.g., immunoprecipitation and Western blots analysis. Any method of binding KSPI1 to IGFs and of purifying the complex can be used in such methods. In a preferred embodiment, KSPI1 or  
 5 fragment thereof may be bound to a chromatographic support, either alone or in combination with other IGFbps, to form an affinity chromatography column. The sample to purify could then be run through this affinity chromatography column.

In another series of embodiments, KSPI1 or fragment thereof can be used to detect and/or to quantify IGFs in a sample. Such methods may then be used in assays and diagnostic kits for the  
 10 quantification of KSPI1-IGF complexes in, e.g., bodily fluids or tissue samples. Any method of detecting the presence or level of KSPI1-IGF complexes can be used. In particular, the methods described by Khosravi *et al* [Clin Chem 43:523-32 (1997)] and in U.S. Patent 6,248,546, which disclosures are hereby incorporated by reference in their entirety, may be adapted. In a preferred  
 15 embodiment, the diagnosis kit, which contains a sample representative of the level of KSPI1-IGF complexes found in a normal subject, can be used to detect diseases caused as a result of impaired IGF level, or to monitor the effects of a treatment aiming to increase or decrease IGF level in a patient.

**Protein of SEQ ID NOS: 82 (Internal designation Clone 517778\_184-5-3-0-G3-F)**

The cDNA of Clone 517778\_184-5-3-0-G3-F (SEQ ID NO:81) encodes the Amyloid

20 Apoptotic Receptor (AAR) protein comprising the amino acid sequence:  
 MAGGVRPLRGLRALCRVLLFLSQFCILSGGESTEIPPYVMKCPSNGLCSRLPADCIDCTTNF  
 SCTYGKPVTFDCAVKPSVTCVDQDFKSQKNFIINMTCRFCWQLPETDYECTNSTSCMTVS  
 CPRQRYPANCTVRDHSVHCLGNRTFPKMLYCNWTGGYKWSTALALSITLGGFGADRFYLG  
 QWREGLGKLFSFGGLGIWTLIDVLLIGVGYPADGSLYI (SEQ ID NO:82). Accordingly, it  
 25 will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:82 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 517778\_184-5-3-0-G3-F. In addition, it will be appreciated that all  
 30 characteristics and uses of the polynucleotides of SEQ ID NO:81 described throughout the present application also pertain to the nucleic acids included in Clone 517778\_184-5-3-0-G3-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:81, SEQ ID NO:82, and Clone 517778\_184-5-3-0-G3-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

AAR is a 221 amino acid receptor with two transmembrane segments. The resulting protein has a hydrophilic intracellular loop and extracellular amino- and carboxy-terminal ends.  
 35 The transmembrane domains and intracellular loop of AAR are very similar to the third and fourth transmembrane domains and intervening sequence of seven transmembrane G protein coupled receptors. The G protein-binding amino acid sequence DRF is found near the first transmembrane

region of AAR. The extracellular portion of AAR binds to ligands that include amyloidgenic peptides. Ligand binding leads to apoptosis for the AAR-expressing cell. AAR has biological activities that comprise binding G protein components and ligands such as amyloidgenic peptides.

Preferred embodiments of the invention include:

- 5 A method of preventing cell death wherein a ligand-binding polypeptide fragment of AAR is contacted with ligand in an amount effective to competitively inhibit ligand binding to AAR expressed on a cell.

Preferred polypeptide fragments of AAR include but are not limited to those starting at an amino acid chosen from amino acids 1- 40 and ending at amino acid chosen from amino acids 165-  
10 180. The most preferred polypeptide fragment comprises amino acids 1-180 of AAR.

Preferred forms of inhibited cell death include those associated with amyloidgenic peptides. A method of inducing apoptotic cell death wherein an AAR ligand is contacted with a cell in an amount effective to induce apoptosis of the cell. Preferred AAR ligands include amyloidgenic peptides. Further preferred AAR ligands are compounds that bind specifically to  
15 AAR and cause apoptosis in the cell expressing AAR. Further preferred AAR ligands include AAR-specific antibodies. Preferred AAR-specific antibodies include those that bind an epitope within the amino-terminal extracellular region of AAR. Preferred cells to be contacted with AAR ligand include neoplastic cells. Further preferred cells include neoplastic cells that express AAR.

A preferred solution of AAR ligand further comprises a hydrogel-forming polymer  
20 solution to improve localization of delivery. A preferred solution of AAR ligand further comprises one or more alkaline salts to improve ligand binding. A preferred solution of AAR ligand further comprises one or more chemotherapeutic agents to improve efficacy of treatment. A preferred method of contacting a cell includes catheter injection.

A preferred method of contacting a cell further includes tumor imaging to improve  
25 accuracy of localized delivery. A preferred method of contacting a cell further includes computer modeling and administration of AAR ligand to improve accuracy of localized delivery.

The amino-terminus of AAR is capable of binding to ligands such as amyloidgenic peptides (i.e., the  $\beta$ -amyloid peptide associated with Alzheimer's disease, Amyloid Precursor Like Proteins (APLP) 1 and 2, immunoglobulin light chain, prealbumin,  $\beta$ -2-microglobulin,  
30 transthyretin, amylin, insulin, atrial natriuretic peptide (ANP), apolipoproteins and glucagon). The amyloidgenic fragments of these proteins form predominantly beta-pleated sheet structures that may adopt the fibrillar configuration of amyloid in certain pathologic states. Amyloid deposits often lead to cell death in affected tissues. Amyloid-associated disorders include, most notably, Alzheimer's disease, diabetes, systemic amyloidosis, familial visceral amyloidosis, cutaneous  
35 amyloidosis, Muckle-Wells syndrome, Gerstman-Straussler disease, dialysis-related and hemodialysis-related amyloidosis. Amyloid deposits may lead to further pathogenic outcomes depending on the affected tissue. For instance, hemodialysis-related amyloidosis can result in

carpal tunnel syndrome, erosive arthropathy, spondyloarthropathy, lytic bone lesions, and pathologic fractures.  $\beta$ -amyloid peptide deposition in the tunica media of leptomeningeal and parenchymal vessels causes degradation of smooth muscle cells and subsequent cortical hemorrhages. Furthermore, the neuronal cell death observed in Alzheimer's disease is associated with the senility that accompanies the later stages of the disease and pancreatic  $\beta$ -islet cell death is a causative factor of disrupted insulin regulation in diabetes. Reducing the level of amyloidgenic peptides is a desired therapy for disorders such as those listed herein.

In a preferred embodiment of the invention, a ligand-binding polypeptide fragment of AAR is used to prevent cell death. This method comprises the step of: contacting a ligand-binding fragment of AAR with ligand in an amount effective to competitively inhibit binding of ligand to AAR expressed on a cell. Preferred polypeptide fragments of AAR include but are not limited to those starting at an amino acid chosen from amino acids 1-40 and ending at an amino acid chosen from amino acids 165-180. Any single AAR fragment or combination of AAR fragments included in said list may be excluded from this embodiment of the invention. The most preferred fragment comprises amino acids 1-180 of AAR. Preferred forms of inhibited cell death include those associated with amyloidgenic peptides, such as pancreatic  $\beta$ -islet cell death and others listed herein. AAR fragments may be applied by methods common to the art such as those discussed herein. For example, AAR fragments may be delivered to cells of the pancreas in physiologically acceptable form by direct injection or catheter. For prolonged treatment, AAR fragments may be released from an implantable polypeptide-releasing stent (U.S. Patent 5683345 and U.S. Patent 5500013, which disclosures are hereby incorporated by reference in their entireties).

In the absence of ligand, AAR expression protects a cell from apoptotic cell death. AAR is expressed in many different cell types, including leukocytes and cells of the heart, brain, placenta, ovaries, testes, lung, liver, muscle, kidney, pancreas, colon, intestine, and prostate. Therefore, AAR may be exploited to cause cell death by addition of ligand. This inducible cell death is useful for treating neoplastic cell growth in a number of different tissues. As a preferred embodiment of the invention, an AAR ligand is used in a method to promote apoptotic cell death. This method comprises the step of contacting an AAR ligand with a cell in an amount effective to induce apoptotic cell death. Preferred AAR ligands include but are not limited to those listed herein (i.e., amyloidgenic peptides). Any single amyloidgenic peptide ligand or combination of amyloidgenic peptide ligands may be excluded from this embodiment of the invention. Further preferred AAR ligands are compounds that bind specifically to AAR and cause apoptosis in the cell expressing AAR, such as an AAR-specific antibody. Preferred antibodies for use in this method include those that bind an epitope within the amino-terminal extracellular region of AAR. Any single antibody or combination of antibodies that bind to an epitope of AAR may be excluded from this embodiment of the invention. Preferred cells to be contacted with AAR ligand include neoplastic cells including but not limited to: neoplastic leukocytes and neoplastic cells of the heart, brain,

placenta, ovaries, testes, lung, liver, muscle, kidney, pancreas, colon, intestine, and prostate.

Further preferred cells include those that express AAR.

Delivery of AAR ligand to specific cells may be accomplished by methods common to the art such as those discussed herein. For example, an effective amount of AAR ligand in physiologically

- 5 acceptable solution may be injected locally by syringe or catheter into a tumor mass to promote apoptotic cell death. AAR ligand may be used as the sole active agent in the solution, or may be used in combination with other chemotherapeutic drugs to increase the efficacy of treatment. A problem with direct delivery of AAR ligand into a solid tumor may be resistance of the tissue to the influx of the fluid. Increased penetration and/or reduced backflow through the point of entry,
- 10 so that more material is introduced into and remains in the tumor, is obtained through the use of a viscous vehicle for the AAR ligand. Preferred materials include solutions or suspensions of a polymeric material which form a hydrogel at the time of or shortly after injection or implantation. The hydrogel solution of AAR ligand is injected via a catheter into regions of the tumor to be treated as described in U.S. Patent 5945100, which disclosure is hereby incorporated by reference
- 15 in its entirety. Another problem with direct delivery of AAR ligand is that cancerous tumors generate localized areas of relatively high acidity due to a metabolic process known as "anaerobic glycolysis." This acidic environment may interfere with ligand binding to AAR. A physiologically acceptable solution of AAR ligand may therefore include a variety of alkaline salts, as described in U.S. Patent 5681857, which disclosure is hereby incorporated by reference in
- 20 its entirety. To further increase the accuracy of treatment, tumor imaging, alone or in combination with computer modeling and administration of the AAR ligand solution may be employed (U.S. Patent 5438989 and U.S. Patent 5823993, which disclosures are hereby incorporated by reference in their entireties).

**Proteins of SEQ ID NOs:84, 86, and 98 (Internal designation Clones 100038\_105-017-4-0-E4-F, 100523\_105-019-1-0-F3-F, and 100545\_105-019-2-0-E3-F)**

The cDNAs of Clones 100038\_105-017-4-0-E4-F and 100523\_105-019-1-0-F3-F (SEQ ID NOs:83 and 85, respectively) encode the Soluble Activator of Wnt (SAW)-1 protein comprising the amino acid sequence:

- MLPPLPSRLGLLLLLLCPAHVGGLWWAVGSPLVMDPTSICRKARRLAGRQAELCQAEPE
- 30 VVAELARGARLGVRECQFQFRFRRWNCSSHKAFGRIQQGQCGEGHPARTLPPRPLGQP
- SRRRFQVPGPS (SEQ ID NOs:84 and 86). The cDNA of Clone 100545\_105-019-2-0-E3-F (SEQ ID NO: 97) encodes the SAW-2 protein comprising the amino acid sequence:

- MLPPLPSRLGLLLLLLCPAHVGGLWWAVGSPLVMDPTSICRKARRLAGRQAELCQAEPE
- VVAELARGARLGVRECQFQFRFRRWNCSSHKAFGRIQQGQCGEGAEVGLLSPCCGTR
- 35 GEENWFAEVA (SEQ ID NO:98). Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NOs:84, 86, and 98 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clones

100038\_105-017-4-0-E4-F, 100523\_105-019-1-0-F3-F, and 100545\_105-019-2-0-E3-F, respectively. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NOs:83, 85, and 97 described throughout the present application also pertain to the nucleic acids included in Clones 100038\_105-017-4-0-E4-F, 100523\_105-019-1-0-F3-F, and 100545\_105-019-2-0-E3-F, respectively. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:83, SEQ ID NO:84, SEQ ID NO:85, SEQ ID NO:86, SEQ ID NO:97, SEQ ID NO:98, Clone 100038\_105-017-4-0-E4-F, Clone 100523\_105-019-1-0-F3-F, and Clone 100545\_105-019-2-0-E3-F. Also preferred are fragments having a biological activity described herein and the polynucleotides encoding the fragments. A preferred

10 fragment of the polypeptides of SEQ ID NOs:84 and 86 comprises:  
 MLPPLPSRLGLLLLLLCPAHVGGLWWAVGSPLVMDPTSICRKARRLAGRQAELCQAEPE  
 VVAELARGARLGVRECQFQFRFRRWNCSSHSKAFGRILQQGQCGEGHPARTLPP. A  
 preferred fragment of the polypeptides of SEQ ID NO:98 comprises:  
 MLPPLPSRLGLLLLLLCPAHVGGLWWAVGSPLVMDPTSICRKARRLAGRQAELCQAEPE  
 15 VVAELARGARLGVRECQFQFRFRRWNCSSHSKAFGRILQQGQCGEGAEVGLLSP. A  
 further preferred fragment of the polypeptide sequences of SEQ ID NOs:84, 86, and 98 comprises:  
 MLPPLPSRLGLLLLLLCPAHVGGLWWAVGSPLVMDPTSICRKARRLAGRQAELCQAEPE  
 VVAELARGARLGVRECQFQFRFRRWNCSSHSKAFGRILQQGQ.

A list of preferred embodiments of the invention follows.

20 A preferred embodiment is a composition, comprising a SAW-1 polypeptide sequence of SEQ ID NO:84.

A preferred embodiment is a composition, comprising a SAW-1 polypeptide sequence of SEQ ID NO:86.

25 A preferred embodiment is a composition, comprising a SAW-1 polypeptide fragment having biological activity.

A preferred embodiment is a composition, comprising a SAW-2 polypeptide sequence of SEQ ID NO:98.

A preferred embodiment is a composition, comprising a SAW-2 polypeptide fragment having biological activity.

30 A preferred embodiment is a composition, comprising a polynucleotide sequence of SEQ ID NO:83 encoding a SAW-1 polypeptide.

A preferred embodiment is a composition, comprising a polynucleotide sequence of SEQ ID NO:85 encoding a SAW-1 polypeptide.

35 A preferred embodiment is a composition, comprising a polynucleotide sequence encoding a biologically active SAW-1 polypeptide fragment.

A preferred embodiment is a composition, comprising a polynucleotide sequence of SEQ ID NO:97 encoding a SAW-2 polypeptide.

A preferred embodiment is a composition, comprising a polynucleotide sequence encoding a biologically active SAW-2 polypeptide fragment.

A preferred embodiment is a method of increasing Wnt-dependent signaling to facilitate stem cell growth comprising the step of: contacting a SAW-1 or SAW-2 polypeptide or

5 biologically active fragment thereof with a stem cell.

Preferred stem cells include those capable of growth or proliferation in response to Wnt.

Further preferred stem cells include those capable of giving rise to hematopoietic cells.

Further preferred stem cells include those capable of giving rise to neuronal or neuroglial cells.

10 Further preferred stem cells include those capable of giving rise to hepatocytes.

Further preferred stem cells include those capable of giving rise to pancreatic cells.

Further preferred stem cells include osteoblasts.

Further preferred stem cells include chondroblasts.

Further preferred stem cells include those found in cord blood.

15 Also preferred is the addition of one or more cell-type specific growth factor to the stem cell before, during or subsequent to contact with SAW-1 or SAW-2 polypeptide.

A preferred embodiment is a method of increasing Wnt-dependent signaling to prevent apoptosis comprising the step of: contacting a SAW-1 or SAW-2 polypeptide or biologically active fragment thereof with a cell at risk of apoptosis.

20 Preferred cells are those capable of responding to Wnt.

Preferably, the method is applied to prevent apoptosis of cells in culture.

Preferably, the method is applied to treat an apoptosis-related disorder.

Preferably, the method is applied to prevent an apoptosis-related disorder.

A preferred apoptosis-related disorder is chosen from the list consisting of:

25 neurodegenerative diseases, Spinal Muscular Atrophy (SMA) types I-III, Amyotrophic Lateral Sclerosis (ALS), Huntington's disease, Alzheimer's disease, Parkinson's disease, retinal degeneration, retinitis pigmentosa, cerebellar degeneration, myelodysplasia, aplastic anemia, ischemia-related degeneration, myocardial infarction, stroke, hepatic degeneration diseases, alcoholic hepatitis, hepatitis B, hepatitis C, fulminant hepatitis, joint degeneration diseases, 30 osteoarthritis, and diabetes.

SAW-1 and SAW-2 are splice variants of the Wnt-6 gene. In the case of SAW-1, the 135-nucleotide cassette inserted into the Wnt-6 cDNA encodes an early termination codon. The resulting SAW-1 polypeptide is 131 amino acids in length, compared to the 365-amino acid Wnt-6 protein. In the case of SAW-2, a 236-nucleotide insertion also encodes for an early termination 35 codon. SAW-2 polypeptide is 129 amino acids in length and possesses a biological activity identical to that of SAW-1. The Wnt family of proteins is crucial for determining cell polarity and fate, patterning of a number of tissues in the developing embryo, cell proliferation, and

maintenance of stem cell populations throughout life. The role of Wnt proteins in promoting cell survival may explain the prevalence of Wnt overexpression in human cancers. Wnt proteins are secreted factors that generally associate with the extracellular matrix or cell surface. Receptors for Wnt proteins include the Frizzled (Fz) family of seven transmembrane spanning receptors and the low-density lipoprotein receptor-related proteins (LRP) 5 and 6. These receptors can act synergistically as Wnt coreceptors to transmit signals and upregulate target gene expression. Inhibitors of Wnt signaling include a soluble form of the Fz receptor, which acts as a competitive dominant negative inhibitor, and the extracellular factors Cerberus and Wnt-Inhibitory Factors (WIFs). Therefore, Wnt proteins are targets for multiple protein-protein interactions. SAW-1 and SAW-2 are novel, truncated splice variants of Wnt-6 that interact with Cerberus and WIF proteins. The biological activities of SAW-1 and SAW-2 are defined by those interactions.

Wnt proteins are important in maintaining stem cell populations throughout adulthood. Stem cells comprise an undifferentiated or partially undifferentiated self-renewing population. As used herein, "stem cell" refers to any cell that retains undifferentiated character, is capable of self-renewal, and that gives rise to a further differentiated cell. These cells are important for renewing cell populations of nearly every type, especially the high-turnover populations of epithelial linings, dermal layers, and the reproductive and hematopoietic systems. Defects in stem cell populations or drastic cell loss, whether caused by genetic predisposition, trauma, injury, disease, or medical treatments such as chemotherapy, have a disastrous effect on an individual. These defects may be overcome by stimulating growth of the remaining stem cell population *in vivo*. Alternatively, *in vitro* culture and transplantation of stem cells, preferably derived from the individual in need of treatment, but also from other sources such as cord blood, may be effective. Mature cells derived from the cultured stem cells may be transplanted as well. As Wnt proteins are effective growth and survival factors for stem cells, these proteins are useful for either strategy of cell replacement. However, Wnt proteins are difficult to purify in soluble form and do not diffuse readily, making Wnt-based treatments difficult to execute. A preferred method of increasing Wnt signaling is to decrease interaction of Wnt with soluble inhibitors such as Cerberus and WIF.

In a preferred embodiment of the invention, a SAW-1 or SAW-2 polypeptide or biologically active fragment thereof is used to increase Wnt-dependent signaling and facilitate stem cell growth. This method comprises the step of contacting a SAW-1 or SAW-2 polypeptide or biologically active fragment thereof with a stem cell. Preferred stem cells include those capable of growth or proliferation in response to Wnt. Also preferred is the addition of one or more cell-type specific growth factors or cytokines in combination with SAW-1 or SAW-2 polypeptide. Examples include the interleukins (e.g., IL-3), granulocyte-macrophage colony-stimulating factor (GM-CSF), macrophage colony-stimulating factor (M-CSF), granulocyte colony-stimulating factor (G-CSF), erythropoietin (Epo), lymphotoxin, steel factor (SLF), tumor necrosis factor (TNF) and gamma-interferon. IL-3 acts on multipotent stem cells as well as progenitors restricted to the

granulocyte, macrophage, eosinophil, megakaryocyte, erythroid or mast cell lineages, while Epo acts on fairly mature erythroid progenitor cells. SAW-1 or SAW-2 polypeptide or a biologically active fragment thereof may be used to facilitate stem cell proliferation in culture by adding a physiologically acceptable solution comprising said polypeptide to a stem cell in culture (e.g., liver

5 stem cells, neural or neuroglial stem cells, osteoblasts, chondroblasts, pancreatic stem cells, hematopoietic stem cells, cord blood, etc.) in an amount effective to promote Wnt-dependent growth or proliferation. A physiologically acceptable solution comprising a SAW-1 or SAW-2 polypeptide or a biologically active fragment thereof may further be added upon transplantation or reintroduction of cultured cells into an individual to provide additional growth potential for the

10 cells *in vivo*. Cell transplantation and reintroduction methods are determined by one skilled in the art and include injection of a single-cell suspension by syringe or catheter and surgical implantation (also see U.S. Patent 5869463 for neuroglial cell transplants; U.S. Patent 6068836 for bone marrow transplants; Noel et al., *Metabolism*, 31:184-7 (1982) for pancreatic cell transplants; and U.S. Patent 4950296, U.S. Patent 5385566, and U.S. Patent 6200324 for bone transplants,

15 which disclosures are hereby incorporated by reference in their entireties). Additionally this method may be applied to increase Wnt-dependent stem cell growth and proliferation *in vivo*. For example, a physiologically acceptable solution comprising SAW-1 or SAW-2 polypeptide or a biologically active fragment thereof may be directly injected to the site of interest (e.g., the bone marrow for hematopoietic stem cell treatment) or by other methods common to the art.

20 Given that stem cells are, at the earliest stage, able to differentiate into almost any kind of mature, functional cell, a wide variety of conditions may be addressed by stem cell treatment. As an example, hematopoietic stem cell growth or replacement may benefit those predisposed to or suffering from, any one or more of the following exemplary conditions: lymphocytopenia; lymphorrhea; lymphostasis; immunodeficiency (e.g., HIV and AIDS); infections (including, for

25 example, opportunistic infections and tuberculosis (TB)); lupus; disorders characterized by lymphocyte deficiency, erythrocytopenia; erthrodegenerative disorders; erythroblastopenia; leukoerythroblastosis; erythroclasis; thalassemia; anemia (e.g., hemolytic anemia, such as acquired, autoimmune, or microangiopathic hemolytic anemia; aplastic anemia; congenital anemia, e.g., congenital dyserythropoietic anemia, congenital hemolytic anemia or congenital hypoplastic

30 anemia; dyshemopoietic anemia; Faconi's anemia; genetic anemia; hemorrhagic anemia; hyperchromic or hypochromic anemia; nutritional, hypoferric, or iron deficiency anemia; hypoplastic anemia; infectious anemia; lead anemia; local anemia; macrocytic or microcytic anemia; malignant or pernicious anemia; megaloblastic anemia; molecular anemia; normocytic anemia; physiologic anemia; traumatic or posthemorrhagic anemia; refractory anemia; radiation

35 anemia; sickle cell anemia; splenic anemia; and toxic anemia); myelofibrosis; thrombocytopenia; hypoplasia; disseminated intravascular coagulation (DIC); immune (autoimmune) thrombocytopenia purpura (ITP); HIV induced ITP; myelodysplasia; thrombocytotic diseases and

thrombocytosis. Stem cells giving rise to neural or neuroglial cells may be applied to treat disorders including but not limited to: Alzheimer's disease, frontotemporal dementia, bipolar disorder, Huntington's chorea, multiple sclerosis, amyotrophic lateral sclerosis, Tay-Sach's disease, Gaucher's disease, and dopamine-related disorders such as Parkinson's disease and schizophrenia. Pancreatic stem cell cultures may be applied to treatment of metabolic disorders such as diabetes. Stem cells from bone tissue (osteoblasts) may be used to treat bone loss, atrophy, or malformation due to injury, congenital or chronic conditions, osteopenia, osteoporosis, rickets, malignant melanoma-induced bone degradation, and bone fissures or fractures due to injury, elective surgery (e.g., plastic surgery), reconstructive surgery, and dental procedures or surgeries.

Wnt proteins act to inhibit apoptosis and promote survival of Wnt-responsive cells. A specific activator of Wnt signaling is desirable both for cell or tissue growth *in vitro* and for treating apoptosis-related disorders *in vivo*. Examples of such disorders include: neurodegenerative diseases such as Spinal Muscular Atrophy (SMA) types I-III, Amyotrophic Lateral Sclerosis (ALS), Alzheimer's disease, Huntington's disease, Parkinson's disease, retinal degeneration, retinitis pigmentosa and cerebellar degeneration; myelodysplasia such as aplastic anemia; ischemic diseases such as myocardial infarction and stroke; hepatic diseases such as alcoholic hepatitis, hepatitis B, hepatitis C, and fulminant hepatitis; joint-diseases such as osteoarthritis; and metabolic disorders such as diabetes. In a preferred embodiment of the invention, a SAW-1 or SAW-2 polypeptide or biologically active fragment thereof is used to prevent apoptosis-related degeneration. This method comprises the step of contacting a SAW-1 or SAW-2 polypeptide or biologically active fragment thereof with a cell. Preferred cells are those capable of responding to Wnt. Further preferred cells are those at risk of apoptosis. For example, a physiologically acceptable composition comprising SAW-1 or SAW-2 polypeptides may be added to a mixed culture of hippocampal neurons to improve cell survival in culture. Alternatively, a physiologically acceptable composition comprising SAW-1 or SAW-2 polypeptide or biologically active fragment thereof may be delivered to an individual diagnosed with or at risk of an apoptosis-related disorder, as determined by one skilled in the art. SAW-1 or SAW-2 polypeptide may be used alone or in combination with agents that modulate Wnt signaling, apoptosis, or cell type-specific processes. Furthermore, SAW-1 or SAW-2 polypeptide may be fused to a ligand for the purpose of stabilizing and/or targeting said polypeptide (for example, tetanus toxin, calcium channel blocking agents, transferrin, poliovirus epitopes, neuropeptide fragments, or steroid hormone androgens, or fragments thereof which are sufficient for neuronal targeting). As an example, a physiologically acceptable composition comprising SAW-1 or SAW-2 polypeptides may be delivered to an individual to prevent osteoarthritis-associated joint degeneration. As an additional example, said composition may be administered to an individual that has or is likely to experience an ischemic event. Appropriate delivery methods, such as those

discussed herein, may be determined on a case by case basis by one skilled in the art.

**Protein of SEQ ID NOs: 88 and 90 (Internal designation Clone 116470\_105-063-3-0-H7-F and Clone 122600\_105-077-3-0-F9-F)**

- The cDNAs of Clone 116470\_105-063-3-0-H7-F and Clone 122600\_105-077-3-0-F9-F (SEQ ID NOs:87 and 89, respectively) encode the Dopamine AMPhetamine INhibitor (Dampin) protein comprising the amino acid sequence:
- MLFRLSEHSSPEEEASPHQRASGEGHHLKSKRPNPCAYTPPSLKAVQRIAESHLQSSISNLNE  
NQASEEDELGELRELGYPREEDEEEEEEDDEEEEEEDSQAENVLKVIKVSAGQKTTCTGQGL  
EGPWERPPPLDESERDGGSEDQVEDPALSEPGEEPQRPSSEPGE (SEQ ID NOs:88 and 90).
- Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NOs:88 and 90 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 116470\_105-063-3-0-H7-F and Clone 122600\_105-077-3-0-F9-F, respectively. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NOs:87 and 89 described throughout the present application also pertain to the nucleic acids included in Clone 116470\_105-063-3-0-H7-F and Clone 122600\_105-077-3-0-F9-F, respectively. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:87, SEQ ID NO:88, SEQ ID NO:89, SEQ ID NO:90, Clone 116470\_105-063-3-0-H7-F and Clone 122600\_105-077-3-0-F9-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

- Dampin is a splice variant of the Dopamine and cAMP-Regulated PhosphoProtein-32 (DARPP-32) that utilizes a different translation start site and lacks the first 37 amino acids of DARPP-32. DARPP-32 is a cytoplasmic signaling molecule that is regulated by phosphorylation at residues T34 by Protein Kinase A (PKA) to function as an inhibitor of Protein Phosphatase 1 (PP1). This increases the effect of PKA on downstream targets. In neurons, PKA phosphorylates DARPP-32 in response to dopamine or psychoactive drugs that act on dopamine signaling pathways (e.g., cocaine and amphetamines). Alternatively, phosphorylation of T75 by Cdk5 results in DARPP-32 inhibition of PKA. Dampin, as a splice variant, is not phosphorylated in response to PKA signaling and does not act as an inhibitor of PP1. However, Dampin has a Cdk5 phosphorylation site and is able to inhibit PKA signaling.

- Abnormal signaling through dopaminergic pathways has been implicated in several major neurological and psychiatric disorders, including Parkinson's disease, Tourette's syndrome, Attention Deficit Disorder (ADD), Huntington's disease, schizophrenia, and drug/ alcohol abuse. In particular, cocaine and amphetamines activate the dopaminergic pathways through PKA. Furthermore, addictive behavior is associated with increased dopaminergic signaling and PKA activity. Therefore, diminished PKA activity may be desired to address addictive behavior and drug and alcohol abuse. Increases in dopamine responses may be desired to treat disorders such as

Parkinson's disease, Tourette's syndrome, ADD, Huntington's disease, and schizophrenia.

Progesterone, similar to dopamine, also activates PKA, which leads to DARPP-32 phosphorylation at T34 and inhibition of PP1. Dampin inhibits both dopamine and progesterone signaling by attenuating PKA activity. Progesterone is required for ovulation and implantation of a fertilized egg in the uterine wall. In addition, progesterone, in combination with dopamine increases female sexual receptivity. Therefore, high levels of Dampin relative to DARPP-32 would be effective for female birth control as well as behavioral modification (e.g., for purposes of animal training). Alternatively, high levels of DARPP-32 relative to Dampin would be effective for increasing female fertility and sexual receptivity.

PP1 activates glycogen synthase in response to insulin. Glycogen synthesis is one mechanism by which blood glucose levels are regulated by insulin. DARPP-32 inhibition of PP1 is in turn inhibited by insulin. However, insufficient insulin or insulin resistance may lead to inappropriate inhibition of PP1 and dysregulation of blood glucose levels. Such dysregulation may result from disorders that include: Noninsulin dependent diabetes mellitus (MIDDM), Insulin dependent diabetes mellitus (IDDM), insulin resistance and insulin resistant disorders such as acanthosis nigricans, leprechaunism, and lipoatrophy. As Dampin does not inhibit PP1, high levels of Dampin relative to DARPP-32 would be effective for modulating blood glucose levels by increasing glycogen synthase activity.

Preferred embodiments of the invention include:

A composition comprising a Dampin polypeptide sequence of SEQ ID NOs:88 and 90. A composition comprising a Dampin polypeptide fragment having biological activity. A composition comprising a polynucleotide sequence of SEQ ID NOs:87 and 89 encoding a Dampin polypeptide. A composition comprising a polynucleotide sequence encoding a Dampin polypeptide fragment having biological activity.

A method of screening test substances for modulators of Dampin expression comprising the steps of: i) contacting a cell with a test substance; and ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell.

A method of screening for test substances that modify the ratio of DARPP-32 relative to Dampin comprising the steps of: i) contacting a cell with a test substance; ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to that of an unexposed control cell; iv) quantifying said expression levels; and v) determining the level of DARPP-32 relative to Dampin in the exposed and unexposed cells.

Preferably, the test substance modifies the ratio of Dampin relative to DARPP-32 in a specific cell type while not in others. Further preferably, the test substance is conjugated to a cell type-specific ligand. Preferably, the method screens for test substances that decrease the ratio of DARPP-32 relative to Dampin.

Alternatively, the method screens for test substances that increase the ratio of DARPP-32 relative to Dampin.

A method of differentiating Dampin polypeptides from DARPP-32 polypeptides comprising the steps of: i) contacting a first antibody that binds specifically to DARPP-32 and not  
5 Dampin with a protein sample; ii) contacting a second antibody that binds specifically to both DARPP-32 and Dampin with a protein sample; and iii) detecting protein-bound antibody. Preferably, the first and second antibodies are labeled with a different detectable conjugate. Preferably, the method follows immunohistochemical protocols.

A substance that decreases the ratio of DARPP-32 relative to Dampin made by the process  
10 comprising the steps of: i) contacting a cell with a test substance; ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to that of an unexposed control cell; iv) quantifying said expression levels; v) determining the level of DARPP-32 relative to Dampin in the exposed and unexposed cells.

15 Preferably, the substance decreases the ratio of DARPP-32 relative to Dampin in a specific cell type while not in others. Further preferably, the substance is contained in a physiologically acceptable composition.

A substance that increases the ratio of DARPP-32 relative to Dampin made by the process comprising the steps of: i) contacting a cell with a test substance; ii) comparing Dampin  
20 expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to that of an unexposed control cell; iv) quantifying said expression levels; v) determining the level of DARPP-32 relative to Dampin in the exposed and unexposed cells.

Preferably, the substance increases the ratio of DARPP-32 relative to Dampin in a specific  
25 cell type while not in others. Further preferably, the substance is contained in a physiologically acceptable composition.

A method of screening for test substances that specifically bind to Dampin and prevent binding to PKA comprising the steps of: i) contacting a test substance with Dampin polypeptide in the presence of PKA, under conditions that allow binding of Dampin to PKA and ii) detecting the  
30 amount of PKA bound to Dampin in the presence and absence of the test substance.

Preferably, the test substance is able to inhibit Dampin interaction with PKA in a certain cell type and not in others. Further preferable are test substances conjugated to cell-type specific ligands or portions thereof.

A substance that specifically binds to Dampin and prevents binding to PKA made by the  
35 process comprising the steps of: i) contacting a test substance with Dampin polypeptide in the presence of PKA, under conditions that allow binding of Dampin to PKA and ii) detecting the amount of PKA bound to Dampin in the presence and absence of the test substance by methods

common to the art.

A method of decreasing PKA activity in a neuron comprising the step of contacting a substance capable of increasing the ratio of Dampin to DARPP-32 with a neuron. Preferably, the substance is capable of passing through the blood brain barrier. Preferably, this method is used to  
5 decrease cocaine- or amphetamine-dependent responses. Preferably, this method is used to diminish addictive behavior. Further preferably, this method is used to diminish alcohol addiction.

A method of decreasing PKA activity in a cell of the female reproductive tract comprising the step of contacting a substance capable of increasing the ratio of Dampin to DARPP-32 with a cell of the female reproductive tract. Preferred cells include ovarian granulosa cells and luteal cells  
10 of the uterus. Preferably, this method is used to inhibit progesterone-dependent ovulation and implantation of a fertilized egg. Preferably, this method is used for female birth control.

A method of modulating blood glucose levels comprising the step of contacting a substance capable of increasing the ratio of Dampin to DARPP-32 with a glycogen-storing cell. Preferred glycogen-storing cells include myocytes and hepatocytes.

15 A method of inhibiting PKA activity comprising the step of introducing a Dampin polypeptide into a cell. Preferably, Dampin polypeptide is delivered to a cell by introducing a polynucleotide encoding Dampin polypeptide into the cell. Preferably, the polynucleotide is a polynucleotide construct comprising an expression control unit and a polynucleotide encoding Dampin polypeptide. Preferred cells include neurons, ovarian granulosa cells, uterine cells,  
20 hepatocytes, and myocytes.

A method of increasing neuronal PKA activity comprising the step of contacting a substance capable of decreasing the ratio of Dampin to DARPP-32 with a neuron. Preferably, the substance is capable of passing through the blood brain barrier. Preferably, this method is used to increase PKA activity in dopaminergic neurons affected by neurological disorders.

25 Preferred neurological disorders include: Parkinson's disease, Huntington's disease, ADD, Tourette's syndrome, and schizophrenia. Preferably, this method is used to increase PKA activity in hypothalamic neurons that express both dopaminergic and progesterone receptors. Preferably, increasing PKA activity in the hypothalamus is directed toward increasing sexual receptivity in a female individual.

30 A method of increasing Atrial Natriuretic Factor (ANF) activity comprising the step of contacting a substance capable of decreasing the ratio of Dampin to DARPP-32 with a nephronic kidney cell. Preferably, this method is used to reduce blood volume. Further preferably, this method is used to reduce hypertension.

An embodiment of the invention provides for a method of screening test substances for  
35 modulators of Dampin expression. This method comprises the steps of: i) contacting a cell with a test substance; and ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell. Dampin expression is determined by methods common to the

art or included herein, by detecting Dampin polynucleotides or polypeptides. An example of this method comprises the steps of: i) culturing two equivalent cell samples; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures at a specified time; iv) purifying the mRNA from each sample of cells; v) comparing the level of Dampin mRNA in each sample by Northern blot, RTPCR, or another method common to the art. The invention provides for design and use of specific polynucleotide probes and primers, as discussed herein. An additional example comprises the steps of: i) having two equivalent cultures of cells; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures; iv) purifying the protein from each sample of cells; v) comparing the level of Dampin polypeptides in each sample by Western blot, immunohistochemistry, or another method common to the art. The invention provides for design and use of specific antibodies and antibody fragments, as discussed herein.

A preferred embodiment of the invention provides a method of screening for test substances that modify the ratio of DARPP-32 relative to Dampin. This method comprises the steps of: i) contacting a cell with a test substance; ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to the test substance to that of an unexposed control cell; iv) quantifying said expression levels; and v) determining the level of DARPP-32 relative to Dampin in the exposed (i.e., test) and unexposed (i.e., control) cells.

A further preferred embodiment of the invention provides a method of screening for test substances that modify the ratio of DARPP-32 relative to Dampin in a specific cell type while not in others. Included in this method are test substances that are conjugated to cell-type specific ligands or portions thereof. For example, a test substance may be conjugated to a hydrophilic neuropeptide (e.g., interferon alpha, endorphin, somatostatin) for targeting to the brain (U.S. Patent 4902505, which disclosure is hereby incorporated by reference in its entirety).

A preferred embodiment of the invention provides a method of screening for test substances that decrease the ratio of DARPP-32 relative to Dampin. An alternative preferred embodiment of the invention provides a method of screening for test substances that increase the ratio of DARPP-32 relative to Dampin.

In a preferred embodiment of the invention, a substance that decreases the ratio of DARPP-32 relative to Dampin is made by the process comprising the steps of: i) contacting a cell with a test substance; ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to that of an unexposed control cell; iv) quantifying said expression levels; v) determining the level of DARPP-32 relative to Dampin in the exposed and unexposed cells. This substance is used for purposes discussed herein.

In a preferred embodiment of the invention, a substance that increases the ratio of DARPP-

32 relative to Dampin is made by the process comprising the steps of: i) contacting a cell with a test substance; ii) comparing Dampin expression in the cell after exposure to the test substance to that of an unexposed control cell; iii) comparing DARPP-32 expression in the cell after exposure to that of an unexposed control cell; iv) quantifying said expression levels; v) determining the level of  
5 DARPP-32 relative to Dampin in the exposed and unexposed cells. The substance that increases the relative level of DARPP-32 is used for purposes discussed herein.

Methods of detecting Dampin polynucleotides and polypeptides may be used to detect DARPP-32 polynucleotides and polypeptides and are addressed herein (e.g., mRNA detection methods, antibody-based detection methods). A simple method for differentiating between the  
10 Dampin and DARPP-32 splice variants is desirable. A preferred embodiment of the invention provides a method for differentiating Dampin polypeptides from DARPP-32 polypeptides. This method comprises the steps of: i) contacting a first antibody that binds specifically to DARPP-32 and not Dampin with a protein sample; ii) contacting a second antibody that binds specifically to both DARPP-32 and Dampin with a protein sample; and iii) detecting protein-bound antibody.  
15 Preferably, the first and second antibodies are labeled with a different detectable conjugate. This allows the method to be carried out with a single protein sample. Preferably, the protein sample is a fixed, semi-permeabilized cell sample. Preferably, the detection method follows immunohistochemical protocols, as discussed herein.

Dampin inhibits PKA by a competitive binding mechanism. Therefore, the inhibitory  
20 effect of Dampin may be ablated by a substance that blocks the interaction of Dampin with PKA. A preferred embodiment of the invention provides a method of screening for test substances that specifically bind to Dampin and prevent binding to PKA. This method comprises the steps of: i) contacting a test substance with Dampin polypeptide in the presence of PKA, under conditions that allow binding of Dampin to PKA (e.g., an intact cell); and ii) detecting the amount of PKA bound  
25 to Dampin in the presence and absence of the test substance by methods common to the art (e.g., antibody-based methods such as coimmunoprecipitation and Western blotting). Preferably, the test substance is able to inhibit Dampin interaction with PKA in a certain cell type and not in others. Included in this method are test substances that are conjugated to cell-type specific ligands or portions thereof.

30 In a preferred embodiment of the invention, a substance that inhibits Dampin binding to PKA is made by the process comprising the steps of: i) contacting a test substance with Dampin polypeptide in the presence of PKA, under conditions that allow binding of Dampin to PKA (e.g., a biological solution, preferably an intact cell); and ii) detecting the amount of PKA bound to Dampin in the presence and absence of the test substance by methods common to the art (e.g.,  
35 antibody-based methods such as coimmunoprecipitation and Western blotting).

In a preferred embodiment of the invention, a substance capable of increasing the ratio of Dampin to DARPP-32 is used in a method to decrease PKA activity in a neuron. Preferred

substances are additionally capable of passing through the blood brain barrier *in vivo*. This method comprises the step of contacting a neuron with said substance. Diminished activity can be measured by an altered modulation of calcium channel function in response to dopamine, *in situ*. This diminished activity may also to be measured as a loss of dopamine-mediated inhibition of the sodium-potassium ATPase (Na,K ATPase) *in situ* or an increased excitability of striatal and cortical neurons. This method may also be applied to: i) diminish release of dopamine in response to amphetamines, as determined *in situ*; ii) diminish release of GABA (4-Aminobutyric acid) in response to amphetamines, as determined *in situ*; iii) increase levels of substance P in the striatum and cortex, as determined *in situ*; iv) increase levels of neurotensin in the striatum and cortex, as determined *in situ*; v) attenuate increase in locomotor activity of an individual in response to cocaine; vi) attenuate increase in the protein Fos in response to an amphetamine, as determined *in situ*; vii) attenuate increase in the protein Chronic Fos Related Antigen (FRA) in response to cocaine, as determined *in situ*; and viii) diminish inhibition of the activity of the brain sodium-potassium-ATPase in response to dopamine, as determined *in situ*; and ix) decrease addictive behavior in an individual at risk of or displaying such behavior, as determined by family history or clinical assessment.

In a preferred embodiment of the invention, a substance capable of increasing the ratio of Dampin to DARPP-32 is used in a method to decrease PKA activity in a cell of the female reproductive tract. This method comprises the step of contacting a cell of the female reproductive tract with said substance. Preferred cells include ovarian granulosa cells and luteal cells of the uterine tract. Dampin inhibits progesterone-mediated PKA activity, which is required for ovulation and implantation of a fertilized egg in the uterine wall. This method is directed toward female birth control.

In a preferred embodiment of the invention, a substance capable of increasing the ratio of Dampin to DARPP-32 in glycogen-storing cells is used to modulate blood glucose levels. This method comprises the step of contacting said substance with glycogen-storing cells. Preferred cells include hepatocytes and myocytes. DARPP-32 inhibits PP1, which is required for glycogen synthase activity in response to insulin. Dampin does not inhibit PP1 and therefore will allow glucose processing and blood glucose modulation. This method is particularly useful for modulating glucose levels in insulin-deficient and diabetic individuals.

As Dampin acts as a dominant negative inhibitor of DARPP-32, Dampin polypeptides may be expressed in a cell to inhibit PKA activity. In a preferred embodiment of the invention, a Dampin polypeptide or polynucleotide encoding said polypeptide is used to inhibit PKA activity in a cell. This method comprises the step of: introducing a Dampin polypeptide or polynucleotide construct comprising an expression control unit operably linked to a Dampin-encoding polynucleotide into a cell. Preferred cells include but are not limited to: neurons, ovarian granulosa cells, uterine cells, hepatocytes, and myocytes. Methods of delivering a polypeptide or

polynucleotide construct to a specific cell type are discussed herein. For example, a polynucleotide construct may be introduced to cells in culture by transfection, electroporation, or viral transduction, as commonly practiced in the art. As a further example, a polynucleotide construct may be introduced to a hepatocyte by packaging said polynucleotide construct into a liposomal vector; targeting the liposomal vector to the liver by embedding a hepatocyte-specific ligand in the membrane (e.g., hepatocyte growth factor); and introducing the liposome in a physiologically acceptable manner to an individual (e.g., orally or by injection). Preferably, this embodiment is directed toward: decreasing addictive behavior, especially in the case of alcohol addiction; reducing cocaine- or amphetamine-dependent responses; reducing progesterone-dependent ovulation and egg implantation; or increasing glycogen synthesis to control blood glucose levels, as discussed herein.

In a preferred embodiment of the invention, a substance capable of decreasing the ratio of Dampin to DARPP-32 is used in a method to increase PKA activity in a neuron. Preferred compounds are additionally capable of passing through the blood brain barrier *in vivo*. This method comprises the step of contacting a neuron with said substance. Deficient dopaminergic signaling (and thus PKA activity) has been implicated in several major neurological and psychiatric disorders, including Parkinson's disease, Tourette's syndrome, ADD, Huntington's disease, and schizophrenia. As DARPP-32 is a vital downstream component the dopaminergic pathway, this method is preferably directed toward treatment of these disorders. Increased activity can be measured by an altered modulation of calcium channel function in response to dopamine, *in situ*, dopamine-mediated inhibition of the sodium-potassium ATPase (Na,K ATPase) *in situ*, an increased excitability of striatal and cortical neurons, or dopamine-mediated inhibition of brain sodium-potassium-ATPase activity, as determined *in situ*. Furthermore, this method may be used to increase sexual receptivity in a female individual. Preferred neurons for use in this method include hypothalamic neurons that express both the dopamine receptor and the progesterone receptor. Preferred individuals include breeding animals. Further preferred individuals include humans.

In a further preferred embodiment of the invention, a substance that blocks the inhibition of PKA by Dampin is used in a method to increase PKA activity in a neuron. Preferred compounds are additionally capable of passing through the blood brain barrier *in vivo*. This method comprises the step of contacting a neuron with said substance. This method is directed toward treatment of neurological and psychiatric disorders, including Parkinson's disease, Tourette's syndrome, ADD, Huntington's disease, and schizophrenia. Furthermore, this method may be used to increase sexual receptivity in a female individual. Preferred neurons for use in this method include hypothalamic neurons that express both the dopamine receptor and the progesterone receptor. Preferred individuals include breeding animals. Further preferred individuals include humans.

- DARPP-32 is required for proper Atrial Natriuretic Factor (ANF) activity in the kidney. ANF modulates blood sodium levels and reduces blood volume by inhibiting the renal sodium-potassium-ATPase, the sole active sodium transporter in the renal basolateral epithelia throughout the nephron. In a preferred embodiment of the invention, a substance capable of decreasing the ratio of Dampin to DARPP-32 expression is used in a method to activate ANF in a cell. Preferred cells are nephronic kidney cells. This method is applied to inhibit the activity of the renal sodium-potassium-ATPase in response to ANF, as determined *in situ*, and increase ANF-mediated sodium excretion *in vivo*. Preferably, this method is directed toward decreasing blood volume and hypertension.
- 10 In a further preferred embodiment of the invention, a substance that blocks the inhibition of PKA by Dampin is used in a method to activate ANF in a cell. Preferred cells are nephronic kidney cells. This method is applied to inhibit the activity of the renal sodium-potassium-ATPase in response to ANF, as determined *in situ*, and increase ANF-mediated sodium excretion *in vivo*. Preferably, this method is directed toward decreasing blood volume and hypertension.
- 15 **Protein of SEQ ID NO:92 (Internal designation Clone 651658\_181-35-2-0-C8-F)**
- The cDNA of clone 651658\_181-35-2-0-C8-F (SEQ ID NO:91) encodes the protein of SEQ ID NO:92, comprising the amino acid sequence:
- MPSSVSWGILLAGLCCLVPVSLAEDPQGDAQKTDTSHTDQDHPTFNKITPNLAFAFSL  
YRQLAHQSNSTNIFFSPVSIATAFAMLSLGTKADTHDEILESINFNLTEIPEAQIHEGFQELL

- 25 Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:92 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in clone 651658\_181-35-2-0-C8-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:91 described throughout the present application also pertain to the nucleic acids included in clone 651658\_181-35-2-0-C8-F. A
- 30 preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:91 and SEQ ID NO:92. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The cDNA of SEQ ID NO:91 is a novel variant of the human alpha 1 anti-trypsin protein named VAGS, encoded by a gene located on chromosome 14, specifically at position 14q32.1.

- 35 The cDNA of SEQ ID NO:91 encodes a 418 amino-acid protein of SEQ ID NO:92.

Proteases are key components of a broad range of biological pathways and can be classified into four groups according to their catalytic mechanisms: the serine, cysteine (thiol),

aspartic (carboxyl), and metalloproteases. VAGS displays serpin motif and thus belongs to the serine protease inhibitor family of protein named serpin. Serpins are irreversible suicide inhibitors of proteases that have a central role in regulating proteolysis in diverse physiological processes such as blood coagulation, fibrinolysis, complement activation, angiogenesis, apoptosis, inflammation, neoplasia and viral pathogenesis. VAGS neutralizes any trypsin formed prematurely within the cells by binding to its active site forming stable complexes with its target enzymes, which is a general property of serpin/serine protease interactions. VAGS is synthesized in the liver and, in response to inflammatory stimuli, inhibits the proteolytic enzyme neutrophil elastase, released from activated neutrophils at sites of inflammation. In hepatocytes, VAGS expression is increased by the cytokine interleukin-6 (IL-6). Synthesis of VAGS is tightly regulated by the net balance of neutrophil elastase and VAGS at sites of inflammation/tissue injury. Alterations of a serpin which can affect its functional levels may result in pathology. Congenital serpin deficiencies cause specific clinical syndromes such as thrombosis with anti-thrombin III deficiency. Individuals with VAGS deficiency are susceptible to premature development of emphysema and liver diseases. In addition, changes in the balance between serine proteases and their cognate inhibitors may lead to pathological states similar to those associated with some neurodegenerative diseases such as Alzheimer's disease.

In one embodiment, VAGS, or fragment thereof, provide an *in vitro* assay to test the specific sensitivity of various proteases to VAGS. The protease inhibitor activity of VAGS may be assessed using any techniques known to those skilled in the art including those disclosed in the US Patent 5,955,284, which disclosure is hereby incorporated by reference in its entirety. Possible substrates for the protein of the invention include, but are not limited to, serine proteases such as elastase, trypsin, chymotrypsin, thrombin III, plasmin, heparin, complement II, plasminogen activator, protein C, interleukin-1beta converting enzyme, preferably trypsin, elastase and chymotrypsin. Methods to assess the activity of such proteases inhibitors include the steps of contacting the inhibitor to be tested with one or several protease substrat in a competition system, and detecting the amount of inhibition of the present protein that occurs. Competitive system can also be used to determine the respective affinities of VAGS among all protease substrates.

In another embodiment, VAGS, or fragment thereof, may be used to remove, identify or inhibit contaminating proteases in a sample. Compositions comprising the polypeptides of the present invention may be added to biological samples as a "cocktail" with other protease inhibitors to prevent degradation of protein samples. The advantage of using a cocktail of protease inhibitors is that one is able to inhibit a wide range of proteases without knowing the specificity of any of the proteases. Using a cocktail of protease inhibitors also protects a protein sample from a wide range of future unknown proteases which may contaminate a protein sample from a vast number of sources. For example, the protein of the invention or fragment thereof are added to samples where proteolytic degradation by contaminating proteases is undesirable. Such protease inhibitor

cocktails are widely used in assays to inhibit proteases susceptible of degrading a protein of interest for which the assay is to be performed. Alternatively, the protein of the invention or fragment thereof may be bound to a chromatographic support, either alone or in combination with other protease inhibitor, using techniques well known in the art, to form an affinity

- 5 chromatography column. A sample containing the undesirable protease is run through the column to remove the protease. Alternatively, the same methods may be used to identify new target proteases of the protein of the invention.

- In one embodiment, VAGS, or fragment thereof, may be useful to quantify the amount of a given protease in a biological sample, and thus used in assays and diagnostic kits for the  
10 quantification of proteases in bodily fluids or other tissue samples, in addition to bacterial, fungal, plant, yeast, viral or mammalian cell cultures. In a preferred embodiment, the sample is assayed using a standard protease substrate. A known concentration of protease inhibitor is added, and allowed to bind to a particular protease present. The protease assay is then rerun, and the loss of activity is correlated to the protease inhibitor activity using techniques well known to those skilled  
15 in the art. Preferred proteases in this embodiment are seine protease, more preferably elastase, trypsin and chymotrypsin.

- In another preferred embodiment, VAGS, or fragment thereof may be used as anti-microbial agent useful to inhibit exogenous proteases implicated in a number of infectious diseases including, but not limited to, bacterial and parasite-borne infections. For example, protease  
20 inhibitors are able to inhibit growth of all strains of group A streptococci, including antibiotic-resistant strains. Accordingly, the present invention may be used to retard or inhibit the growth of certain microbes either in vitro or in vivo.

- The present invention provides a method for identify other molecules which specifically binds VAGS. For example, the composition of the balance proteases/proteases inhibitors of a  
25 diseased tissue can be determined by isolating the present protein under conditions that do not disrupt protein-protein interactions, and determining the identity of proteins associated with the present protein. Such associated proteins can be identified by any standard method including, but not limited to, immunoprecipitation and immuno-affinity columns. It can also comprise an investigation using the yeast-2-hybrid trap for identification of new interactions involving relevant  
30 targets of the present protein that could be implicated in some diseases affecting serpin biology.

Another method can comprise the combination of the present protein with the library of molecules under conditions suitable to allow complex formation, and detecting complex formation, wherein the presence of the complex identifies a molecule which specifically binds the protein of the invention and that could be accumulated in some disorders.

- 35 In a further embodiment, VAGS provides a method of producing a recombinant serpin capable of effectively modulating serine protease activity. Despite the availability of human alpha 1 anti-trypsin from serum, quantities large enough for therapeutic uses have been unobtainable, due

in large part to the limited availability of human serum. Consequently, there is a great need for other sources of alpha 1 anti-trypsin to fill the needs created by therapeutic uses. In one preferred embodiment, milkers animal can be used to produce the protein of the invention in the milk, thereby generating a significant amount of this particular protein after purification. Any type of animal that produce enough quantity of milk can be used in this aim such as, but not limited to, sheep, goat, and cow. These animals can be generated with any method of targeting overexpression of the present protein in the milk. Also in this embodiment, the protein of the invention can be produced in host cells that have been transfected with an appropriate expression vector comprising a nucleic acid sequence coding for the present protein. The host cells are cultured under conditions whereby the nucleic acid sequence coding for this particular protein is expressed. After a suitable amount of time for the product to accumulate, the protein is purified from the host cells or medium surrounding the cells. Introduction of an expression vector incorporating a nucleic acid sequence coding for the protein of the invention into a host cell can be performed in a variety of ways, such as but not limited to calcium or lithium chloride treatment, electroporation, lipofection.

In another embodiment, use of VAGS provides a method of effectively modulating serine proteases activity in cells. For example, the level or activity of the present protein can be increased in cells to decrease the rate or inhibit specific serine proteases by contacting the biological sample with an amount of the present protein sufficient to decrease the rate or inhibit specific serine proteases of one or more cells within the sample, or with a compound that increases the activity or expression of the present protein within one or more cells of the sample. Such methods can be performed either *in vitro* or *in vivo*. The level of the present protein can be increased in cells in any of a number of ways, including by administering purified protein to the cells, transfecting the cells with a polynucleotide encoding the protein, or administering a compound to the cells that causes an increase in the activity or expression of the protein. Alternatively, serine proteases level can be increase by decreasing the level of the present protein in cells, for example using antisense molecules, or more specifically inhibit the activity of the present protein using direct or indirect inhibitor molecules or antagonistic antibodies directed against the present protein.

The present invention also provides animal models generated by modulating the expression or activity of the present protein in one or more tissues of the animal. Such animals are useful for a number of purposes, for example to assist with the study of the human alpha 1 anti-trypsin deficiency disease, because they represent an *in vivo* assay method for testing candidate molecules potentially useful for the treatment of various pathophysiological aspects of diseases specifically related to the activity of the present protein. Study of the phenotype of such models can also allow the identification of additional human equivalent diseases caused by or linked with alpha 1 anti-trypsin deficiency. These animals can be generated with any method of targeting overexpression or inactivation of the present protein. Such models are extremely useful, e.g. in the assessment of

candidate therapies and drugs for the treatment of inflammatory diseases and conditions.

In other embodiment, VAGS, or fragment thereof, is used to diagnose diseases or disorders associated with altered expression or activity of the present protein. In particular, it is useful in diagnosing patients with deficient amounts of the present invention which results in uncontrolled activity of target proteases. Examples of such diseases and disorders include, but are not limited to, alpha 1 anti-trypsin deficiency associated disorders and more specifically liver diseases, or diseases associated with an excess level of elastase, such as rheumatoid arthritis, emphysema, and psoriasis. The method includes the steps of contacting a fluid or tissue sample obtained from an individual suspected of suffering from the disease or condition, or at risk of developing the disease or condition, with a compound capable of selectively binding the present protein or nucleic acids, e.g. a polyclonal or monoclonal antibody or any immunologically active fragment thereof, a nucleic acid probe, etc., and detecting the level, or any other detectable property of the present protein in the sample, where a difference in the level or other property in the sample relative to in a control sample indicates the presence of the disease or disorder, or of a propensity for developing the disease or disorder. In this embodiment, the identification of mutations using well known PCR or RT-PCR techniques and in particular in with real time PCR system that could facilitate diagnosis of such conditions. Alternatively, using such a method, the present invention provides a tool to correlate modulations in the expression of the specific variant of the invention with some pathologies which have never been linked to. Thus, the present invention provides a novel candidate gene for such conditions.

A further embodiment of the present invention is to provide novel methods and compositions useful for the treatment of diseases and conditions related to the abnormal function of proteases or their inhibitors. The VAGS, or fragment thereof, may be used to inhibit proteases implicated in a number of diseases where cellular proteolysis occur such as diseases characterized by tissue degradation preferably including, but not limited to, arthritis, muscular dystrophy, inflammation, tumor invasion, glomerulonephritis, parasite-borne infections, Alzheimer's disease, periodontal disease, and cancer metastasis. The methods and compositions can also be useful for treatment of septic shock, pancreatitis, coagulation disorders. In a more preferably embodiment, the invention relates to compositions and methods to use the protein of the invention or fragment thereof in diseases characterized by an abnormally elevated levels of trypsin, chymotrypsin, or elastase, including but not limited to, chronic emphysema of the lungs, cirrhosis, liver diseases, cystic fibrosis, and more specifically for alpha 1 anti-trypsin deficiency associated disorders such as aneurysm or toxic shock. In this embodiment, the present invention is preferably applied in the treatment of diseases associated with an excess level of elastase, such as rheumatoid arthritis, emphysema, and psoriasis. Indeed, uncontrolled secretion of elastase which frequently results from aging of the cells or genetic defects may cause non-specific proteolysis and trigger destructive processes associated with those various chronic diseases. Such methods comprise the

administration of a therapeutically-effective amount of the present protein to mammals suffering from the disease or condition, where "effective amount" is meant a concentration of the present protein which is capable of modulating the activity of serine proteases. The compositions of the invention are preferably delivered to the affected mammals in combination with a physiologically acceptable liquid, such as a saline solution or other buffer, or physiologically acceptable carrier. For treatment of skin inflammation, the compositions of the invention may be applied to the affected area in combination with a physiologically acceptable ointment or cream. The proportional ratio of active ingredient to pharmaceutical carrier will naturally depend on the chemical nature, solubility, and stability of the recombinant serine protease inhibitor. The particular amount of the compositions of the invention that will be administered to the mammal for any particular condition will depend on the clinical condition of the patient and the type of illness, and other factors such as the weight, age, the patient and route of delivery. Such composition can be administered by any suitable route including, but not limited to, intravenous, intramuscular, intraperitoneal, subcutaneous routes, and topically to an affected area of the skin or by absorption through epithelial or mucocutaneous linings such as nasal, oral, vaginal, rectal. Alternatively, for treatment purposes, the protein of the invention may be administered using any of the gene therapy methods known in the art. These compositions can comprise the protein of the invention, and, optionally, one or more other types of protease inhibitors, or any other compound of interest. Indeed, in this embodiment, the present invention find use in drug potentiation applications. For example, therapeutic agents such as antibiotics or antitumor drugs can be inactivated through proteolysis by endogenous proteases, thus rendering the administered drug less effective or inactive. Accordingly, the protease inhibitor of the invention may be administered to a patient in conjunction with a therapeutic agent in order to potentiate or increase the activity of the drug. This co-administration may be by simultaneous administration, such as a mixture of the protease inhibitor and the drug, or by separate or sequential administrations. All of these components may be either obtained from natural sources or produced by recombinant genetic engineering techniques and/or chemical modification.

Since the regulation of serine proteases by their inhibitors are critical for the control of tissue destruction in the diseases described above, in a further embodiment, VAGS, or fragment thereof provides an assay for the monitoring of markers in vivo for characterisation of disease states. The invention thus includes test kits useful for the quantification in a biological sample of the amount of the present protein. The kits comprise at least one immunological binding partner, e.g. a monoclonal or polyclonal antibody specific for the protein of the invention and coupled to detectable markers. In this embodiment, the application of such assays can be used to monitor the progress of therapy administered to treat these or other conditions. Further, the assays can be used as a measure of toxicity, or during clinical testing of new drugs to assess the impact on tissue degradation. Thus the assays may be applied in any situation wherein the present invention can be

used as an index of the condition, treatment, or effect of substances directly administered to the subject or to which the subject is exposed in the environment. This marker may thus also play a role as prognostic indicators, preferably concerning inflammatory diseases. For example, it can be used in the Alzheimer's disease where chronic inflammation is an accompanying physiological contributor to this multifactor pathology. Also in a preferred embodiment, the present invention provides a method of detecting the presence and/or monitoring the metastatic progress of a malignancy. Indeed, metastatic potential can be influenced by the interaction between the neoplastic cells and their microenvironment such as extracellular matrix and proteolytic enzymes including the present protein. The invention thus includes test kits useful for quantify the amount of the present protein in a biological sample comprising the steps of contacting the biological sample with a specific monoclonal or polyclonal antibody specific for the present protein and coupled to detectable markers. Thus, the condition of a patient can be monitored continuously and the quantified amount of such proteins measured in the pathological sample can be compared with the amount quantified in a biological sample of a normal individual or with the previous analysis of the same patient. In all this embodiment, this marker can be measured effectively in plasma, serum or blood, by any suitable method, including immunoassays. It can also preferably be measured in tissues and fluids recovered from inflammatory sites. Thus, the condition of a subject can be monitored continuously and the quantified amount of this particular protein measured in the pathological sample can be compared with the amount quantified in a biological sample of a normal individual.

**Polynucleotides of SEQ ID NO:93 (Internal designation Clone 150011\_110-006-3-0-D5-F) and SEQ ID NO:95 (Internal designation Clone 500737461\_205-43-3-0-E3-F)**

TTTCACTATGATTTTCTATTTTCTTCTAAAATGCTTTTAATTAATATGTTTCATTAAATT  
TTCTATGCTTATTGCAAAAAAAAAAAAAAAAAA. Accordingly, it will be appreciated that all

characteristics and uses of the polynucleotides of SEQ ID NO:95 and polypeptides of SEQ  
IDNO:96 described throughout the present application also pertain to the nucleic acids included in  
5 Clone 500737461\_205-43-3-0-E3-F. Clone 500737461\_205-43-3-0-E3-F is alternatively referred  
to herein as TFPI-M162Qfs in reference to the nucleotide polymorphism that is a subject of the  
present invention. A preferred embodiment of the invention is directed toward the compositions of  
SEQ ID NO:95, SEQ ID NO:96, and Clone 500737461\_205-43-3-0-E3-F. Also preferred are  
polypeptide fragments having a biological activity as described herein and the polynucleotides  
10 encoding the fragments.

The extrinsic coagulation pathway is initiated on exposure of Tissue factor (TF) to plasma  
(McVey JH, Bailliere's Clinical Haematology 12:361-72 (1999) which disclosure is hereby  
incorporated by reference in its entirety). Tissue Factor Pathway Inhibitor-1 (TFPI-1) is a negative  
regulator of the extrinsic coagulation pathway (US Patent 5,849,875 which disclosure is hereby  
15 incorporated by reference in its entirety).

TFPI-1 is a secreted trivalent Kunitz-type plasma proteinase inhibitor. TFPI-1 negatively  
regulates the initiation of coagulation through a mechanism of activated factor X (FXa) feedback  
inhibition of the catalytic complex of activated factor VII (FVIIa) and TF. That is, TFPI-1 directly  
inhibits FXa and, in a FXa-dependent fashion, produces feedback inhibition of the TF-FVIIa  
20 complex by allosteric enablement of TF-FVIIa binding. TFPI-1 is the major inhibitor of the  
protease activity of the TF-FVIIa complex. The second Kunitz domain of TFPI-1 binds and  
inhibits FXa, whereas the first Kunitz domain is responsible for the inhibition of FVIIa in the TF-  
FVIIa complex. The function of the third Kunitz domain is unknown, although there is evidence  
that it contains a heparin binding site. Heparin binding site(s) have also been mapped carboxyl-  
25 terminal to the third Kunitz domain.

Tissue factor pathway of coagulation plays a dominant role during normal haemostasis.  
TFPI-1, expressed primarily by the microvascular endothelium, appears to be the major  
physiologic inhibitor of TF-induced coagulation. TF-initiated coagulation also plays an important  
role in the pathophysiology of many diseases, including coronary thrombosis, disseminated  
30 intravascular coagulation, stroke, and atherosclerosis. Several animal studies have found a  
beneficial effect of recombinant TFPI-1 in some of these clinical conditions.

TFPI-1 plays an important role in modulating TF-dependent thrombogenesis.  
Recombinant full-length TFPI-1 prevents thrombosis formation and rethrombosis after lysis in a  
rabbit model of jugular vein thrombosis (Kaiser, B et al. Thromb. Haemost. 76:615-20 (1996)  
35 which disclosure is hereby incorporated by reference in its entirety). In a rat model of  
disseminated intravascular coagulation, TFPI-1 was found to inhibit thrombus formation (Elsayed,  
YA et al., Am. J. Clin. Pathol. 106:574-83 (1996) which disclosure is hereby incorporated by

reference in its entirety).

High levels of TF antigen and activity are detected in atherosclerotic lesions, particularly in the advanced lesions. When the plaques are ruptured or eroded, exposure of cellular and extracellular TF to circulating blood plays a pivotal role in mediating fibrin-rich thrombus formation leading to acute coronary syndromes. Presence of TFPI-1 in atherosclerotic plaques is associated with reduced tissue factor activity and reduced plaque thrombogenicity (Caplice, NM et al., *Circulation* 98:1051-7 (1998); Badimon, JJ et al., *Circulation* 99:1780-7 (1999) which disclosures are hereby incorporated by reference in their entirety).

An recent study in mice using the gene knockout technology unambiguously established that deficiency of TFPI-1 promotes atherosclerosis and thrombosis. In this work, it was found that TFPI-1 protects from atherosclerosis and is an important regulator of the thrombosis that occurs in the setting of atherosclerosis (Westrick, RJ et al., *Circulation*, 103:3044-6 (2001) which disclosure is hereby incorporated by reference in its entirety). Importantly, it was found that in this model inactivation of only one of the two copies of the TFPI-1 gene was sufficient to promote atherosclerosis and thrombosis.

Recently several amino acid polymorphisms have been identified for human TFPI-1. A mutation at nucleotide position 1 of exon 7 results in the substitution of leucine for proline at position 179 (numbered from the initiating methionine of TFPI-1) (Kleesiek, K et al., *Blood* 10:3976-7 (1998) which disclosure is hereby incorporated by reference in its entirety). This mutation occurs immediately downstream of Kunitz domain 2 (US Patent 5,849,875 which disclosure is hereby incorporated by reference in its entirety). This mutation has been found to be statistically associated with a higher risk for venous thrombosis (Kleesiek, K et al., *Thromb. Haemost.* 82:1-5 (1999) which disclosure is hereby incorporated by reference in its entirety).

A second amino acid polymorphism results in the substitution of methionine for valine at position 292 (numbered from the initiating methionine of TFPI-1). This mutation occurs very near the carboxy-terminus of TFPI-1. As might be expected for a mutation so far downstream of Kunitz domains 1 and 2, no link was found between this mutation and venous thromboembolic disease (Arnaud, E et al., *Thromb. Haemost.* 82:159-60 (1999) which disclosure is hereby incorporated by reference in its entirety).

The cDNA of clone 150011 encodes the protein of SEQ ID NO:94. In the case of TFPI-C16Pfs, a deletion of two nucleotides in codon 16 (numbered from the initiating methionine of TFPI-1) results in the substitution of proline for cysteine and in the introduction of a frame-shift leading to premature termination of the protein within the signal sequence (exon 3). Specifically, whereas codon 16 of TFPI-1 reads TGC (US Patent 5,849,875 which disclosure is hereby incorporated by reference in its entirety), in TFPI-C16Pfs nucleotides T and G have been deleted. As protein TFPI-C16Pfs terminates upstream of Kunitz domains 1 and 2, the protein of SEQ ID NO:94 is nonfunctional.

The cDNA of clone 500737461 encodes the protein of SEQ ID NO:96. In the case of TFPI-M162Qfs, a deletion of two nucleotides in codon 162 (numbered from the initiating methionine of TFPI-1) and mutation of the remaining nucleotide results in the substitution of glutamine for methionine and in the introduction of a frame-shift leading to premature termination of the protein within Kunitz domain 2 (exon 6). Specifically, whereas codon 162 of TFPI-1 reads ATG (US Patent 5,849,875 which disclosure is hereby incorporated by reference in its entirety), in TFPI-M162Qfs two of the nucleotides have been deleted and the third changed to C. As protein TFPI-M162Qfs terminates within Kunitz domain 2, neither FXa binding nor the consequential enablement of TF-FVIIa-binding by Kunitz domain 1 occurs, leading to nonfunctional protein of SEQ ID NO:96.

The availability of informative genetic screenings and diagnostic markers for genetic predisposition to thrombosis would be of considerable value. On one hand, said information can be used by the patient to make appropriate lifestyle changes. On the other hand, said information can be used by the physician to anticipate thrombotic complications that might arise in the course of clinical procedures. In both cases, said information results in health benefit to the patient and in reduced medical costs borne by the patient as well as by society in general.

The nucleotide polymorphisms that are described herein for clones 150011 (TFPI-C16Pfs) and 500737461 (TFPI-M162Qfs) and that are the subject of the present invention lead to nonfunctional TFPI-1. There is clear evidence that having even just one of the two copies of the TFPI-1 gene inactivated predisposes the patient to atherosclerosis and thrombosis. It follows therefore that the nucleotide polymorphisms described here within the coding region of TFPI-1 that lead to nonfunctional TFPI-1 have genetic screening and diagnostic value in identifying patients that are genetically predisposed to atherosclerosis and thrombosis.

In a preferred embodiment, the present invention provides for a method of diagnosing genetic predisposition to atherosclerosis and thrombosis through the identification of a dinucleotide deletion in TFPI-1 codon 16 (numbered from the initiating methionine of TFPI-1). Methods of identifying such a dinucleotide deletion are well known to those skilled in the art and include, but are not restricted to, to PCR-SSCP (polymerase chain reaction followed by single-strand conformation polymorphism) (Kleesiek, K et al., Blood 10:3976-7 (1998) which disclosure is hereby incorporated by reference in its entirety).

In a further preferred embodiment, the present invention is drawn to a method of determining if an individual is at increased risk of developing atherosclerosis and thrombosis comprising the step of identifying a dinucleotide deletion in TFPI-1 codon 16 (numbered from the initiating methionine of TFPI-1), preferably using the method of PCR-SSCP, in a biological sample, preferably blood, wherein said deletion indicates increased risk.

In additional preferred embodiment, the present invention provides for a method of diagnosing genetic predisposition to atherosclerosis and thrombosis through the identification of a

dinucleotide deletion in TFPI-1 codon 162 (numbered from the initiating methionine of TFPI-1). Methods of identifying such a dinucleotide deletion are well known to those skilled in the art and include, but are not restricted to, to PCR-SSCP (polymerase chain reaction followed by single-strand conformation polymorphism) (Kleesiek, K et al., Blood 10:3976-7 (1998) which disclosure is hereby incorporated by reference in its entirety).

In a further preferred embodiment, the present invention is drawn to a method of determining if an individual is at increased risk of developing atherosclerosis and thrombosis comprising the step of identifying a dinucleotide deletion in TFPI-1 codon 162 (numbered from the initiating methionine of TFPI-1), preferably using the method of PCR-SSCP, in a biological sample, preferably blood, wherein said deletion indicates increased risk.

Protein of SEQ ID NO:100 (Internal designation Clone 479155\_174-4-4-0-C8-F)

The cDNA of clone 479155\_174-4-4-0-C8-F (SEQ ID NO:99) encodes the protein of SEQ ID NO:100 comprising the amino acid sequence

MIVKGVASRTVVS RPFPGNWLFSS IQLTDDQGPVLM TTVAMPVFSKQNETRSKGILLGVV  
 15 GTDVPVKELLKTIPKYKLGIHGYAFAITNNGYILTHPELRLLYEEGKKRRKPNYSSVDLSE  
 VEWEDRDDVLRNAMVNRKTGKFSMEVKKTVDKGVHFSQTFLLNLKQTTVKN.

Accordingly it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:100 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 479155\_174-4-4-0-C8-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:99 described throughout the present application also pertain to the nucleic acids included in Clone 479155\_174-4-4-0-C8-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:99, SEQ ID NO:100, and Clone 479155\_174-4-4-0-C8-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

25 The protein of SEQ ID NO:100 encodes ADEVAR, a variant of calcium channel  $\alpha$ 2delta3 subunit resulting from alternative splicing. ADEVAR has novel function as described below.

Alpha2delta3 subunit is a component of voltage-gated  $\text{Ca}^{2+}$  channels. The  $\alpha$ 2 subunit has several hydrophobic sequences, but biosynthetic studies indicate that it is an extracellular, 30 extrinsic membrane protein attached to the membrane through disulfide linkage to the delta subunit. The delta subunit is encoded by the 3' end of the coding sequence of the same gene as the  $\alpha$ 2 subunit, and the mature forms of these two subunits are produced by post-translational proteolytic processing and disulfide linkage (Catterall, WA, Annu. Rev. Cell Dev. Biol. 16:521-55 (2000) which disclosure is hereby incorporated by reference in its entirety). Alpha2delta3 subunit 35 is expressed exclusively in the brain (Klugbauer, N et al., J. Neuroscience 19:684-691 (1999) which disclosure is hereby incorporated by reference in its entirety). Alpha2delta3 subunit plays a role in regulating neuronal  $\text{Ca}^{2+}$  currents (Catterall, WA, Annu. Rev. Cell Dev. Biol., 16:521-55

(2000); Stefani, A et al., *Neuropharmacology* 37:83-91 (1998) which disclosures are hereby incorporated by reference in their entirety). Alpha2delta3 subunit has been implicated in epileptic seizures (Gee NS et al., *J. Biol Chem.* 271:5768-76 (1996); Bryans JS et al., *J. Med. Chem.* 41:1838-1845 (1998) which disclosures are hereby incorporated by reference in their entirety).

- 5 ADEVAR is a product of alternative splicing leading to a soluble protein truncated at both its amino- and carboxyl-termini. ADEVAR plays a negative regulatory role in Ca<sup>2+</sup> channel function. Diminished ADEVAR expression leads to dysregulated Ca<sup>2+</sup> flux through the channel and reduced neuronal excitability.

- In a preferred embodiment, the present invention provides for an antibody that specifically  
10 binds ADEVAR of the present invention. Further preferred is a method of making said antibody wherein said antibody recognizes a non-conformational or conformational epitope of ADEVAR.

- Further preferred is a method wherein a mouse is immunized with ADEVAR. Further preferred is said immunization with ADEVAR, wherein ADEVAR is produced by recombinant DNA methodology. Further preferred is a method wherein monoclonal antibodies from said  
15 mouse are screened for binding to ADEVAR but not to full-length alpha2delta3 subunit. Further preferred is a method wherein monoclonal antibodies derived from said mouse are screened by enzyme-linked immunosorbent assay (ELISA) for binding to ADEVAR but not to full-length alpha2delta3 subunit. Methods of expressing protein by recombinant DNA methodology are well known to those skilled in the art. Methods of generating said monoclonal antibody and of  
20 establishing specificity by methods including ELISA are well known to those skilled in the art.

- In a further preferred embodiment, the present invention provides for a method wherein said ADEVAR antibody is used in a method of quantitating ADEVAR in bodily fluid. Further preferred is a method of quantitating ADEVAR in bodily fluid, wherein the method of quantitation is a sandwich ELISA format. Further preferred is a method wherein said ADEVAR antibody is  
25 used to measure ADEVAR concentration in cerebrospinal fluid. In a preferred embodiment, the present invention provides for a method of contacting said antibody and specifically binding it with ADEVAR. Further preferred is a method for using said antibody diagnostically to stratify seizures and thereby add value to therapeutic strategies. Further preferred is a method of diagnosis, wherein reduced ADEVAR level is associated with predisposition to seizure in a subset of patients  
30 manifesting seizure.

**Protein of SEQ ID NO:102 (Internal designation Clone 586587\_181-9-2-0-C5-F)**

The cDNA of Clone 586587\_181-9-2-0-C5-F (SEQ ID NO: 101) encodes hABC of SEQ ID NO:102, comprising the amino acid sequence:

- MACWPQLRLLLWKNLTFRRRQTCQLLLEVAWPLFIFLILISVRLSYPPYEQHECHFNPKNAM  
35 PSAGTLPWVQGIICNANNPCFRYPTPGEAPGVVGNFNKSIVARLFSDARRLLLYSQKDTSM  
KDMRKVLRTLQQIKKSSSRGDKRHFLNWQKGLKPLPQALL. Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:102 described

throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 586587\_181-9-2-0-C5-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NOs:101 described throughout the present application also pertain to the nucleic acids included in Clone 586587\_181-9-2-0-C5-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:102, SEQ ID NO:101, and Clone 586587\_181-9-2-0-C5-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments. hABC is a novel splice variant of the ATP-binding cassette 1. As a splice variant, hABC is only 162 amino-acid long whereas ABCA1 is 2261 amino acid long. hABC displays 100% identity with ABCA1 over its 140 amino-terminal residues, whereas the 22 carboxyl-terminal amino acids are unique to hABC. hABC does not display the Walker A and B motifs nor the active transport signature. The 140 common amino acids correspond to the cytoplasmic amino-terminal tail of ABCA1 that plays a role in cholesterol-binding. Furthermore, hABC displays one transmembrane domain (TCQLLLEVAWPLFIFLILISV) and a "positive-hydrophobic-polar" signal peptide that is required for translocation to the plasma membrane. Moreover, the hABC splice variant is specifically expressed in liver cells. Thus, hABC plays an important role in clearing HDL from the bloodstream by binding to HDL-cholesterol, thus allowing HDL-cholesterol import to liver cells where lipids are catabolized and excreted.

An embodiment of the invention is directed to a composition comprising a hABC polypeptide sequence of SEQ ID NO:102.

A further embodiment of the invention is directed to a composition comprising a hABC polypeptide fragment having biological activity.

An embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO:101 encoding a hABC polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a hABC polypeptide fragment having biological activity.

An embodiment of the invention is directed to a composition comprising a polynucleotide sequence that yields an RNA that is complementary to the sequence of SEQ ID NO:101 encoding a hABC polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence that yields an RNA that is complementary to a polynucleotide sequence encoding a hABC polypeptide fragment. Preferred such a polynucleotide sequence is the polynucleotide sequence that yields an RNA that is complementary to GAGGGGACAAACGCCATTCCTCAACTGGCAGAAGGGACTGAAGCCTCTCCCTCAAG CCCTTTTA.

A further embodiment of the invention is directed to compositions comprising an antibody directed against a hABC polypeptide or against a hABC polypeptide fragment having the same

biological activity. Preferably, the antibody specifically binds to the hABC polypeptide or and not to the ABCA1 polypeptide. Even more preferably, the antibody recognizes the LQQIKKSSSRGDKRHFL amino-acid sequence or the RHFLNWQKGLKPLP amino-acid sequence.

5 An embodiment of the present invention relates to methods of measuring the circulating HDL-cholesterol in bodily fluids. Methods of detecting measuring the circulating HDL-cholesterol comprise the steps of i) labeling by standard methods of the hABC polypeptide with a molecule which can be used to provide a quantifiable signal, ii) addition of this probe, under conditions suitable for the formation of hybridization complexes, to a fluid obtained from a patient  
10 and to control fluids containing a known amount of HDL-cholesterol, iii) washing of the samples, after a suitable incubation period, in order to remove all hABC polypeptides that are not complexed with HDL-cholesterol, and iv) comparison of the resulting signal with control samples containing a known amount of HDL-cholesterol. Such methods can be used in diagnostic kits for detecting diseases associated with low circulating HDL-cholesterol level, for evaluating the  
15 efficacy of a particular therapeutic treatment regimen in animal studies and in clinical trials, and for monitoring the treatment of an individual patient. The binding efficiency of hABC to HDL-cholesterol can be determined using any technique familiar to those skilled in the art, e.g. using the assay described in U.S. Patent 5,962,322, which disclosure is hereby incorporated by reference in its entirety.

20 An embodiment of the present invention relates to compositions comprising an antibody directed against hABC or fragment thereof, and to a method to decrease uptake of HDL-cholesterol comprising the step of inhibiting hABC binding to HDL-cholesterol using an anti-hABC antibody. Preferably, such compositions comprise the preferred antibodies described above. Such compositions can be administered to a cell, a tissue sample or a patient. Preferably, this method is  
25 directed to treating an individual with low circulating HDL-cholesterol level by decreasing HDL-cholesterol clearance.

Another embodiment relates a method to decrease uptake of HDL-cholesterol comprising the step of inhibiting hABC expression without affecting ABCA1 expression using an antisense polynucleotide. In such a method, recombinant expression vectors comprising a polypeptide that  
30 yields an RNA that is complementary to the sequence of the hABC mRNA can be administered to cell, a tissue sample or a patient. Preferred such an antisense polynucleotide is described above. Preferred expression vectors include viral vectors, especially adenoviral and lentiviral vectors. Preferably, the antisense polynucleotides of the present invention are administered to hepatocytes.

In another embodiment, genetic modification of a cell with a vector comprising a  
35 polynucleotide that yields an RNA that is complementary to the sequence of the hABC mRNA may be accomplished using one or more techniques well known in the gene therapy field. For example, one of the methods described in Mulligan (Mulligan, Science, 260:926-32 (1993)), which

disclosure is hereby incorporated by reference in its entirety, can be used. Preferably, such a method is directed to treating an individual with low circulating HDL-cholesterol level by decreasing HDL-cholesterol clearance.

A further embodiment of the present invention is directed to substances that decrease hABC expression without affecting ABCA1 expression, and to a method of screening for such substances comprising the steps of: i) contacting a cell with a test substance, ii) comparing hABC expression in the cell after exposure to that of an unexposed control cell, iii) comparing ABCA1 expression in the cell after exposure to that of an unexposed control cell, iv) quantifying said expression levels, and v) determining the ratios of hABC and ABCA1 expression in an exposed cell relative to the expression in an unexposed cell. Preferably, hABC expression is studied in an hepatocyte and ABCA1 expression is studied in a macrophage.

In another preferred embodiment, compositions comprising substances that decrease hABC expression without affecting ABCA1 expression can be administered to patients presenting low levels of HDL-cholesterol.

Additionally, the compositions comprising an antibody directed against hABC or substances that decrease hABC expression without affecting ABCA1 expression can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration to patients. For example, the pharmaceutical composition comprising an antibody directed against hABC substances that decrease hABC expression without affecting ABCA1 expression may be made up in a solid form (e.g. granules for oral administration, powders for inhalation) or in a liquid form (e.g. solutions for oral administration or for injection).

Effectiveness of the compositions can be verified *in vivo* by measuring the plasma HDL-cholesterol level of an animal model before and after administration of the composition of the present invention. The circulating HDL-cholesterol level can for example be measured using the fast pressure liquid chromatography technique as described in U.S. Patent 5,962,322, which disclosure is hereby incorporated by reference in its entirety. The dosage regimen for treating a human patient presenting low circulating HDL-cholesterol with compositions of the present invention may vary widely, but can be determined using standard methods. For example, the amount of antibody directed against or substances that decrease hABC expression without affecting ABCA1 expression is an amount sufficient to increase circulating low HDL-cholesterol in the plasma of a subject.

The compositions of the invention may be administered alone or in combination with other known agents increasing circulating HDL-cholesterol level, e.g., gemfibrozil, niacin and the SR-BI HDL-cholesterol receptor. Diseases associated with low circulating HDL-cholesterol level that may be treated by compositions and methods of the present invention include, but are not limited to, arteriosclerosis, angioplasty, dyslipidemia associated with non insulin-dependant diabetes mellitus, obesity and various other coronary artery diseases.

**Protein of SEQ ID NO:104 (Internal designation Clone 620315\_188-13-1-0-G12-F)**

The cDNA of Clone 620315\_188-13-1-0-G12-F (SEQ ID NO: 103) encodes MOBP-81h of SEQ ID NO:104, comprising the amino acid sequence:

MSQKPAKEGPRLSKNQKYSEHFSIHCCPPFTFLNSKKEIVDRKYSICKSGCFYQKKEEDWI

5 CCACQKTRLKRKIRPTPKKK. Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:104 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 620315\_188-13-1-0-G12-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NOs:103 described throughout the present application also pertain to the nucleic acids  
10 included in Clone 620315\_188-13-1-0-G12-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:104, SEQ ID NO:103, and Clone 620315\_188-13-1-0-G12-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of the present invention, named MOBP-81h, is a novel splice variant of the  
15 myelin-associated oligodendrocytic basic protein (MOBP, Genbank accession number BAA05659). MOBP-81h is only 81 amino acids long, whereas MOBP is 183 amino acids long. The first exon is identical between the two cDNAs. MOBP-81h lacks the second exon of MOBP, and the twelve carboxyl-terminal amino acids of MOBP-81h are unique to this splice variant. MOBP-81h, is the first splice variant described for the human MOBP protein. MOBP-81h is  
20 specifically expressed in CNS oligodendrocytes, and plays a role in maintaining myelin sheath integrity.

An embodiment of the invention is directed to a composition comprising a MOBP-81h polypeptide sequence of SEQ ID NO:104.

A further embodiment of the invention is directed to a composition comprising a MOBP-  
25 81h polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO:103 encoding a MOBP-81h polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a MOBP-81h polypeptide fragment having biological activity.

30 In another embodiment, the compositions of the present invention comprise MOBP-81h polypeptides. The method of producing MOBP-81h polypeptides comprises the steps of: i) transfecting a mammalian host cell with a recombinant expression vector comprising a polynucleotide of the present invention, and ii) purifying the produced protein. The purification of the protein can be done following any technique well-known to those skilled in the art. Preferably,  
35 an antibody directed against MOBP-81h or fragment thereof may be bound to a chromatographic support to form an affinity chromatography column. Even more preferably, the antibody recognizes the twelve carboxyl-terminal amino acids of MOBP-81h.

An embodiment of the present invention relates to methods of using the polypeptides and the polynucleotides of the present invention to treat or to reduce in severity demyelinating disorders. Any compositions and methods containing, e.g., MOBP-81h polypeptide or fragment thereof, a polynucleotide encoding the protein, or a compound that increases the expression or activity of MOBP-81h can be used.

In an embodiment, the methods of the present invention relate to the administration of a recombinant expression vector comprising one of the polynucleotides of the invention to a patient suffering from a demyelinating disease. Preferred expression vectors include viral vectors, especially adenoviral and lentiviral vectors.

In another embodiment, genetic modification of a cell with a vector comprising one of the polynucleotides of the invention may be accomplished using one or more techniques well known in the gene therapy field. For example, one of the methods described in Mulligan (Mulligan, Science, 260:926-32 (1993)), which disclosure is hereby incorporated by reference in its entirety, can be used.

In still another embodiment, the compositions of the present invention comprise a substance that increases MOBP-81h expression.

Additionally, the methods of the present invention relate to methods of screening test substances that increase MOBP-81h expression. These methods comprise the steps of: i) contacting a cell with a test substance; and ii) comparing MOBP-81h expression in the cell after exposure to the test substance to that of an unexposed control cell. Preferably, the test substance modifies the expression of MOBP-81h in oligodendrocytes while not in other cell types.

Effectiveness of compositions and methods of the present invention to treat demyelinating diseases can be verified in vitro by studying the effects of the compositions of the present invention on the morphology of myelin sheaths by immunoelectron microscopy. Effectiveness of compositions and methods of the present invention to treat demyelinating diseases can be verified in vivo using experimental models of demyelinating disorders, e.g., TMEV-infected mice. Effective doses of the polypeptides or polynucleotides of the present invention for treating a patient suffering from demyelinating disorders can be determined according to the relevant techniques. For example, the effective amounts of compositions of the present invention can be determined by measuring the necessary and sufficient amount of composition for disappearance or reduction in severity of clinical manifestations associated with demyelinating disorders (e.g. tremor, tonic seizure, unstable locomotion, ataxia).

In a preferred embodiment, MOBP-81h polypeptides or a substance that increases MOBP-81h expression can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration to patients. Thus, the pharmaceutical composition comprising MOBP-81h or fragment thereof or a substance that increases MOBP-81h expression may be made up in a solid form (e.g. granules for oral administration, powders for inhalation) or in a liquid form

(e.g. solutions for oral administration or for injection).

The compositions of the invention may be administered alone or in combination with other known agents treating demyelinating disorders, e.g., imidazol derivatives or MBP molecules.

Demyelinating disorders that may be treated by a composition containing MOBP-81h or fragment thereof include but are not limited to leukodystrophies (e.g. Krabbe's disease, metachromatic leukodystrophy, ALD, Canavan disease, Alexander disease), leukoencephalopathies, multiple sclerosis and virus-induced inflammatory demyelination.

**Protein of SEQ ID NO: 106 (Internal designation Clone 646477\_181-19-2-0-F4-F)**

The cDNA of Clone 646477\_181-19-2-0-F4-F (SEQ ID NO:105) encodes novel

- 10 Apolipoprotein H (NAPOH) of SEQ ID NO:106, comprising the amino acid sequence:  
MISPVILFSSFLCHVAIAGRTPKPDLPFSTVVPLKTFYEPGEEITYSCKPGYVSRGGMRK  
FICPLTGLWLINTLKCTPRVCPFAGILENGAVRYTTFEYPNTISFSCNTGFYLNAGDSAKCT  
EEGKWSPPELVCAPII CPPSIPTFATLRVYKPSAGNNSLYRDTAVFECLPQHAMFGNDTIT  
CTTHGNWTKLPECREVKCPFPSRPDNGFVNYPKPTLYYKDKATFGCHDGYSLDGPEEIE
- 15 CTKLGNWSAMPSCKASCKVPVKKATVVYQGERVKIQEKFKNGMLHGDKVSFFCKNKEK  
KCSYTEDAQCIDGTIEVPKCFKEHSSLAFWKTDASDVKPC. Accordingly, it will be  
appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:106 described  
throughout the present application also pertain to the polypeptides encoded by the nucleic acids  
included in Clone 646477\_181-19-2-0-F4-F. In addition, it will be appreciated that all
- 20 characteristics and uses of the polynucleotides of SEQ ID NO:105 described throughout the  
present application also pertain to the nucleic acids included in Clone 646477\_181-19-2-0-F4-F. A  
preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:105,  
SEQ ID NO:106, and Clone 646477\_181-19-2-0-F4-F. Also preferred are polypeptide fragments  
having a biological activity as described herein and the polynucleotides encoding the fragments.
- 25 The protein of SEQ ID NO:106 is a polymorphic variant of the sequence of apolipoprotein  
H or beta-2-glycoprotein I precursor (swissprot accession numberP02749). Like apolipoprotein H,  
the protein of the invention displays 4 Sushi domains (PF00084) and one sushi-like domain, from  
amino acids 23 to 79 (Sushi 1), amino acids 84 to 137 (Sushi 2), amino acids 142 to 200 (Sushi 3),  
amino acids 205 to 260 (Sushi 4) and amino acids 263 to 345 (Sushi-like). Sushi domains are also
- 30 known as Complement control protein (CCP) modules, or short consensus repeats (SCR), exist in a  
wide variety of complement and adhesion proteins. Also, it has been reported that the domain V  
(sushi-like domain) specifically interacts with hydrophobic ligands (Hong, D.P. et al.,  
Biochemistry 40:8092-8100 (2001)). Novel apolipoprotein H, the protein of SEQ ID NO:106, is  
highly expressed in liver.
- 35 Novel apolipoprotein H is a plasma protein with the ability to bind with various kinds of  
negatively charged substances. Novel apolipoprotein H (NAPOH) may prevent activation of the  
intrinsic blood coagulation cascade by binding to phospholipids on the surface of damaged cells.

NAPOH is a strong auto-antigen that stimulates a vigorous B cell-humoral response and T cell immunity response. NAPOH has been implicated in a variety of physiologic pathways including lipoprotein metabolism, atherosclerosis and in the production of antiphospholipid autoantibodies ("aPA"). NAPOH also binds to platelets, mitochondria, heparin, DNA, and anionic phospholipids, and has been shown to be involved in the blood coagulation pathway, platelet aggregation, and prothrombinase activity of platelets. NAPOH exerts multiple inhibitory effects on the coagulation pathway and platelet aggregation. NAPOH is considered to be a required cofactor for anionic phospholipids antigen by the aPA found in sera of many patients with chronic inflammatory disease, like systemic lupus erythematosus, and primary antiphospholipid syndrome, but it does not seem to be required for the reactivity of aPA associated with infections. These studies suggest that the NAPOH-phospholipid complex forms the antigen to which aPA are directed. Autoantibodies to phospholipid-free NAPOH are present in patients with primary antiphospholipid syndrome. Antiphospholipid autoantibodies are a heterogeneous group of autoantibodies including most commonly a lupus anticoagulant and anticardiolipin antibodies which are directed against negatively charged phospholipids. The presence of antiphospholipid autoantibodies has been associated with recurrent deep vein thrombosis and other thrombotic complications, including pulmonary, renal, and retinal thrombosis, as well as Budd-Chiari syndrome. In addition, antiphospholipid autoantibodies have been associated with arterial thrombosis including cerebral, retinal, and peripheral arteries. Recurrent fetal losses, usually occurring in the second and third trimester, felt to be due in part to thrombosis of the placental vessels and subsequent infarction resulting in placental insufficiency and ultimately fetal loss are associated with antiphospholipid autoantibodies.

An embodiment of the invention is directed to a composition comprising a novel Apolipoprotein H (NAPOH) polypeptide sequence of SEQ ID NO: 106.

A further embodiment of the invention is directed to a composition comprising a NAPOH polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO: 105 encoding a NAPOH polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a NAPOH polypeptide fragment having biological activity.

Preparation and purification of the protein of SEQ ID NO:106 or fragments thereof may be carried out as described in Patent US-5,859,213, the disclosure of which is incorporated herein by reference in its entirety. For example, a method of purifying NAPOH from human blood plasma comprising the steps: i) heating and cooling the plasma to obtain a precipitate and a supernatant, ii) separating the supernatant and acidifying the supernatant, iii) adding a precipitation agent to the supernatant and separating aqueous albumin solution from second precipitate, iv) subjecting the aqueous albumin solution to affinity chromatography; and v) eluting the particulate support to

obtain NAPOH.

A further embodiment of the invention is directed to a method of screening test substances for activators or inhibitors of NAPOH expression comprising the steps of: i) contacting a cell with a test substance; and ii) comparing NAPOH expression in the cell after exposure to the test substance to that of an unexposed control cell. As a result, such NAPOH activators are of great potential as new drugs due to their ability to induce coagulation and are expected to be useful in treatment of various coagulation disorders (including but not limited to hereditary disorders, such as hemophilias and disseminated intravascular coagulation, a severe hemorrhagic syndrome) or to enhance coagulation and other hemostatic events in treating wounds resulting from trauma, surgery or other causes. Alternatively, such NAPOH inhibitors can be useful in treatment of autoimmune diseases and thrombotic diseases.

A further embodiment of the invention is directed to a method of screening for test substances that specifically bind to NAPOH and prevent binding to antiphospholipid autoantibodies to comprising the steps of: i) contacting a test substance with NAPOH polypeptide in the presence of antiphospholipid autoantibodies, under conditions that allow binding of NAPOH to antiphospholipid autoantibodies and ii) detecting the amount of antiphospholipid autoantibodies bound to NAPOH in the presence and absence of the test substance by methods common to the art. Preferably, the test substance is able to inhibit NAPOH interaction with antiphospholipid autoantibodies. Interaction of NAPOH with autoantibodies is linked to antiphospholipid syndrome and more specifically to autoimmune arterogenesis.

A further embodiment of the invention is directed to a method of screening substances for modulators of NAPOH expression comprising the steps of: i) contacting a cell with a test substance; and ii) comparing NAPOH expression in the cell after exposure to the test substance to that of an unexposed control cell. NAPOH expression is determined by methods common to the art or included herein, by detecting NAPOH polynucleotides or polypeptides. An example of this method comprises the step of: i) culturing two equivalent cell samples; ii) adding a test substances to one of the cultures and not the other; iii) harvesting both cultures at a specified time; iv) purifying the mRNA from each sample of cells; v) comparing the level of NAPOH mRNA in each sample by Northern Blot, RTPCR, or another method common to the art. The invention provides for design and use of specific polynucleotide probes and primers, as described herein. An additional example comprises the step of: i) having two equivalent cultures of cells; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures; iv) purifying the protein from each sample of cells; v) comparing the level of NAPOH polypeptides in each sample by Western blot, immunohistochemistry, or another method common to the art. The invention provides for design and use of specific antibodies and antibody fragments, as discussed herein. As a result, such NAPOH activators are of great potential as new drugs due to their ability to induce coagulation and are expected to be useful in treatment of various coagulation disorders

(including but not limited to hereditary disorders, such as hemophilias and disseminated intravascular coagulation, a severe hemorrhagic syndrome) or to enhance coagulation and other hemostatic events in treating wounds resulting from trauma, surgery or other causes.

Alternatively, such NAPOH inhibitors can be useful in treatment of autoimmune diseases and thrombotic diseases by decreasing the level of inflammatory aPAs. In another embodiment, the invention relates to methods for using the protein of the invention or fragments to identify autoantibodies which are related to autoimmune disease and systemic lupus erythematosus (SLE). Accordingly, the present protein may be used to detect the presence of autoantibodies. In a typical embodiment, the protein of SEQ ID NO:106 is labeled with any detectable moiety including, but are not limited to, a fluorescent label, a radioactive atom, a paramagnetic ion, biotin, a chemiluminescent label or a label which can be detected through a secondary enzymatic or binding step. The invention further provides a method of diagnosing SLE, and distinguishing such processes from other diseases.

An antagonist of the protein of SEQ ID NO:106 may be produced using methods which are generally known in the art. The antagonist will affect the binding activity of NAPOH to negatively charged phospholipids which are implicated in autoimmune disorders. In one aspect, the protein of the invention or a fragment thereof may be used to synthesize specific antibodies using any techniques known to those skilled in the art including those described therein. In particular, purified NAPOH may be used to produce antibodies or to screen libraries of pharmaceutical agents to identify those which specifically bind NAPOH. NAPOH may thus be used for the characterization and assay of antibody against this protein in patients suffering from autoimmune disorder.

The ability of the protein of the invention or fragment thereof to function as a major antigen for antiphospholipid antibodies may be assessed using techniques well known to those skilled in the art. The ability of the protein of the invention or fragment thereof, especially fragments containing Sushi motifs and Sushi-like motifs, to bind to antiphospholipid autoantibodies may be assessed using techniques well known to those skilled in the art including those described herein. For example, the protein of SEQ ID NO:106 or a fragment thereof may be fixed to a solid support, such as a chromatography matrix. A preparation containing antiphospholipid autoantibodies is placed in contact with the protein of the invention under conditions which facilitate binding to NAPOH. The support is washed and then the antiphospholipid autoantibodies are released from the support by contacting the support with agents which cause antiphospholipid autoantibodies to dissociate from the NAPOH.

An embodiment of the present invention relates to methods of using the protein of the invention or fragment thereof, particularly polypeptides containing Sushi motifs, or derivative thereof to identify and/or quantify binding autoantibodies, preferably anti phospholipid autoantibodies, in a biological sample, and thus used in assays and diagnostic kits for the

quantification of such binding proteins in bodily fluids, in tissue samples, and in mammalian cell cultures. Such assays may be particularly useful as diagnostic or prognostic tools in the detection and monitoring of a disorder linked to primary antiphospholipid syndrome. The binding activity of the protein of the invention or fragment thereof may be assessed using any method familiar to those skilled in the art. Preferably, a defined quantity of the protein of the invention or fragment thereof is added to the sample under conditions allowing the formation of a complex between the protein of the invention or fragment thereof and the binding protein to be identified and/or quantified. Then, the presence of the complex and/or the free protein of the invention or fragment thereof is assayed and eventually compared to a control using any of the techniques known by those skilled in the art.

In another embodiment, an array of oligonucleotides probes comprising the nucleotide sequence of SEQ ID NO:105 or fragments thereof can be constructed to conduct efficient screening of e.g., genetic mutations. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to identify genetic variants, mutations, and polymorphisms. This information may be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents (see for example: Chee, M. et al., Science, 274:610-614 (1996) which disclosure is hereby incorporated by reference in its entirety). For example, it has been shown that genetic variants, mutations, and polymorphisms are related to thrombotic related disease and chronic inflammatory disease (described in U.S. Pat. Nos: 6,203,980 B1, the disclosure of which is incorporated herein by reference in its entirety).

In addition, NAPOH is involved in the fertilization process. The addition of the purified protein to prepared sperm samples from normospermic men increases significantly the straight line velocity (VSL) and the amplitude of lateral head displacement (ALH). Storage of sperm is of widespread importance in commercial animal breeding programs, human sperm donor programs, and in the treatment of certain disease states. For example, sperm samples may be frozen for men who have been diagnosed with cancer or other diseases that may eventually interfere with sperm production, as well as for assisted reproduction purposes where sperm may be stored for use at other locations or times. The procedures utilized in such cases include: washing a sperm sample to separate out the sperm-rich fraction from non-sperm components of a sample such as seminal plasma or debris; further isolating the healthy, motile sperm from dead sperm or from white blood cells in an ejaculate; freezing or refrigerating of sperm for use at a later date or for shipping to females at differing locations; extending or diluting sperm for culture in diagnostic testing or for use in therapeutic interventions such as in vitro fertilization or intracytoplasmic sperm injection (Cohen et al. 12: 994-1001 (1997)). Once sperm have been washed or isolated, they are then extended (or diluted) in culture or holding media for a variety of uses (sperm analysis, diagnostic tests, assisted reproduction). Each of these uses for extended or diluted sperm requires a somewhat different

formulation of basal medium (see, for review, US Patent No. 6,140,121 Ellington et al. Oct. 2000); however, in all cases sperm survival is suboptimal outside of the female reproductive tract. Novel additional components of a dilution or storage medium which could improve the functional preservation of sperm would be useful. Therefore, in another preferred embodiment of this invention, purified recombinant proteins encoded by SEQ ID NO:106 or fragments thereof can be added as components of pharmacological media designed to protect spermatozoa. The methods used to compose such preservation media are generally known by those skilled in the art (for example, Oliver S.A., et al. US patent 5,897,987 Apr.1999; Cohen J. et al., supra). Inversely, in yet another embodiment of this invention, ligands, inhibitors, neutralizing antibodies or other biological agents which recognize the protein of the invention and which bind it and which block it can be used as components of pharmacological formulations designed for male contraception purposes.

**Protein of SEQ ID NO:108 (Internal designation Clone 113165\_105-056-3-0-G12-F)**

The cDNA of clone 113165 (SEQ ID NO:107) encodes the protein of SEQ ID NO:108, comprising the amino acid sequence:

MAAGGSGVGGKRSSKSDADSGFLGLRPTSDPALRRRRRGPRNKKRGWRRRLAQE  
 PLGLEVDQFLEDVRLQERTSGGLLSEAPNEKLFFVDTGSKEKGLTKKRTKVQKSLLLKK

 APDIDVQLSSELTDRLTLKPEGNLRDRFKSFQRRNMIEPRERAKFKRKYVKLVKRAFR  
 REIQL. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:108 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in clone 113165\_105-056-3-0-G12-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:107 described throughout the present application also pertain to the nucleic acids included in clone 113165\_105-056-3-0-G12-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:107, SEQ ID NO:108, and clone 113165\_105-056-3-0-G12-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The cDNA of SEQ ID NO:107 is a novel human JNK3-binding protein named hJNK3-BP, homologous to a murine JNK3-binding protein (GSP:AAB12882). The cDNA of SEQ ID NO:107 encodes a 478 amino-acid protein of SEQ ID NO:108, which is predominantly expressed in the brain.

The c-Jun NH2-terminal kinase (JNK) signal transduction pathway is activated in response

to various environmental stress and by the engagement of several classes of cell surface receptors. In mammalian cells, JNK has been implicated in the immune response, oncogenic transformation and apoptosis. These effects of JNK are mediated, at least in part, by increased gene expression. Three mammalian genes encode JNK protein kinases. JNK1 and JNK2 are expressed ubiquitously, while JNK3 is expressed primarily in the brain (Ip YT, Davis RJ Curr Opin Cell Biol 1998 Apr;10(2):205-19). By performing a yeast two-hybrid screen specifically with JNK3 as a bait, Ito M, *et al.* (Ito M, Yoshioka K, Akechi M, Yamashita S, Takamatsu N, Sugiyama K, Hibi M, Nakabeppu Y, Shiba T, Yamamoto KI. Mol Cell Biol 1999 Nov;19(11):7539-48) isolated mouse Jsap1 (for JNK/stress-activated protein kinase-associated protein 1), also known as Jip-3 (Kelkar N, Gupta S, Dickens M, Davis RJ, Mol Cell Bio 2000 20:1030-1043). Jip-3 represents a JNK-interacting proteins (JIPs), such as Jip-1 and Jip-2, acting as scaffolding proteins that may regulate signal transduction by the JNK signaling pathway. The protein of the invention hJNK3-BP specifically binds JNK3 protein kinase, modulating the biological effects of JNK3 signaling pathway in cells. hJNK3-BP represents the founding member of a new class of scaffold protein involved in the regulation of the JNK3 cascade.

An embodiment of the invention is directed to a composition comprising a hJNK3-BP polypeptide sequence of SEQ ID NO:108.

A further embodiment of the invention is directed to a composition comprising a hJNK3-BP polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO:107 encoding a hJNK3-BP polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a hJNK3-BP polypeptide fragment having biological activity.

In one embodiment, the present invention provides a method of producing a recombinant protein capable of effectively modulating JNK activity. The protein of the invention can be produced in host cells that have been transfected with an appropriate expression vector comprising a nucleic acid sequence coding for hJNK3-BP polypeptides. Introduction of an expression vector incorporating a nucleic acid sequence coding for the protein of the invention into a host cell can be performed in a variety of ways, including but not limited to calcium or lithium chloride treatment, electroporation, or lipofection. Any of a wide variety of expression systems can be used to provide the recombinant proteins. Suitable expression vehicles include, but are not limited to plasmids, viral particles and baculovirus for insect cells. The expression vehicle can be integrated into the host cell genome. In some circumstances, it is desirable to employ an inducible expression vector. The host cells harboring the expression vehicle are cultured in conventional nutrient media, under conditions whereby the nucleic acid sequence coding for this particular protein is expressed. After a suitable amount of time for the product to accumulate, the protein is purified from the host cells.

In another embodiment, the present invention provides a method of effectively modulating JNK activity in cells. The level or activity of hJNK3-BP can be increased in cells to decrease or inhibit specific JNK protein kinase activity, thereby preventing JNK3-associated apoptosis. hJNK3-BP levels may be increased by introducing hJNK3-BP polynucleotides or polypeptides into a cell in an amount sufficient to specifically inhibit JNK protein kinase activity of one or more cells within the sample. Such methods can be performed either *in vitro* or *in vivo*. The level of hJNK3-BP can be increased in cells in any of a number of ways. For instance, purified hJNK3-BP protein may be introduced to the cells by microinjection or by liposome or micelle-mediated transport. Such liposomal or micellar microcapsule may optionally be combined with a cell type-specific target, such as an antibody or receptor ligand. Alternatively, hJNK3-BP polynucleotides may be introduced to a cell by methods common to the art such as transfection, electroporation, or viral transduction. Cyclodextrin, liposome or micelle-mediated transport may also be used to introduce hJNK3-BP polynucleotides to a cell. Useful examples of the above methods are described in U.S. Patents 5019369, 5616565, 6110490, 6204060, and P.C.T. WO9704748, disclosures of which are hereby incorporated by reference in their entireties. In addition, any compound that increases the expression of hJNK3-BP polypeptides can be used to decrease JNK protein kinase activity within one or more cells of the sample. Such compounds can be identified by screening for test substances that increase hJNK3-BP expression comprising the steps of: contacting a cell with a test substance and comparing hJNK3-BP expression in the cell after exposure to the test substance to that of an unexposed control cell.

The present invention provides an *in vitro* method to inhibit apoptosis induced by JNK activation to keep cells alive in culture. Preferably, the present invention is suited to the culturing of cells for purposes including transplantation or implantation of such cells *in vivo* after an *ex vivo* introduction of hJNK3-BP polynucleotides. Said polynucleotides may be introduced to a cell of interest by methods known in the art, such as those listed above. Furthermore, such a method can be used with neurons or other cell types which undergo apoptosis in culture. Transplantation of healthy neurons expressing a hJNK3-BP into subjects whose neurons are degenerating can alleviate some effects of the neuronal diseases or disorders. Treated cells can be grafted, in particular, into the brain, either as cells cultured *in vitro* on a support matrix using techniques disclosed in the US Patent 6,264,943, which disclosure is hereby incorporated by reference in its entirety, or as dispersed cells.

The present invention also provides animal models generated by modulating the expression or activity of the present protein in one or more tissues of the animal. Preferably, the expression of hJNK3-BP polypeptides is targeted in the brain. The transgene can be integrated as a single transgene or in concatamers, e.g., head-to-head tandems or head-to-tail tandems. The transgene can also be selectively introduced into and activated in a particular cell type using a conditional expression system. Such animals are useful for a number of purposes, because they represent an *in*

*vivo* assay method for testing candidate molecules potentially useful for the treatment of various pathophysiological aspects of diseases specifically related to the activity or consequence of the activity of hJNK3-BP polypeptides on JNK biological effects. Study of the phenotype of such models can also allow the identification of additional human diseases associated with JNK

- 5 abnormal activity. These animals can be generated with any method of targeting overexpression or inactivation of hJNK3-BP to produce the founder lines of transgenic animals. Such models are extremely useful, e.g. in the assessment of candidate therapies and drugs for the treatment of neurodegenerative diseases and autoimmune or malignancy conditions.

- In other embodiment, the protein of the invention or fragment thereof is used to diagnose  
10 diseases or disorders associated with abnormal hJNK3-BP activity and in particular with altered JNK biological effects. In particular, it is useful in diagnosing patients with deficient amounts of hJNK3-BP which results in uncontrolled activity of JNK protein kinase and monitor hJNK3-BP expression in such conditions. Preferably, the present invention provides a method of diagnose pathologies linked to altered apoptosis or inflammatory responses such as, but are not limited to,  
15 neurodegenerative diseases characterized by apoptosis, including Parkinson's disease and Alzheimer's disease, autoimmune diseases such as arthritis or other conditions characterized by inflammation and malignancies such as leukemias. The method comprises the steps of contacting a tissue sample obtained from an individual suspected of suffering from the disease or condition or at risk of developing the disease or condition, with a detectably labeled compound capable of  
20 selectively binding hJNK3-BP polypeptides or nucleic acids. For example, a polyclonal or monoclonal antibody or any immunologically active fragment thereof or a nucleic acid probe may be used.

- This marker may thus also play a role as prognostic indicators, preferably concerning inflammatory diseases. More preferably, it can be measured in tissues and fluids recovered from  
25 inflammatory sites. Thus, the condition of a subject can be monitored continuously and the quantified amount of this particular protein measured in the pathological sample can be compared with the amount quantified in a biological sample of a normal individual or with previous samples of the same patient.

- A further embodiment of the present invention is to provide novel methods and  
30 compositions useful for the treatment or prevention of diseases and conditions related to the abnormal JNK biological effects and preferably with abnormal apoptosis. The protein of the invention or fragment thereof may be used to treat neurodegenerative diseases characterized by apoptosis, including Parkinson's disease and Alzheimer's disease. Other conditions that can be treated using the compositions and methods of the invention are autoimmune diseases such as  
35 arthritis, other conditions characterized by inflammation such as inflammatory arthritis and bronchial asthma, and malignancies such as, but not limited to leukemias.

In another embodiment of the present invention is to provide novel methods and

compositions useful for the treatment or prevention of diseases and conditions associated with oxidative damage dependent on abnormal JNK biological effects. The protein of the invention or fragment thereof can be used to treat or prevent oxidative damage to organs such as the liver and kidney, and in particular, damage due to ischemia/reperfusion in heart disease and

- 5 cardiomyopathy. More preferably, such methods and compositions can also be used to treat donor organs for transplantation. Indeed these organs are exposed to substantial environmental stress which can affect the normal functioning of the organs; effects of which can be blocked by JNK modulators such as hJNK3-BP.

- Such methods comprise the administration of a therapeutically-effective amount of hJNK3-BP
- 10 polypeptides to mammals suffering from the disease or condition, where "effective amount" is meant a concentration of hJNK3-BP polypeptides which is capable of modulating JNK biological effects. The compositions of the invention are preferably delivered to an individual in combination with a pharmaceutically acceptable carrier, such as a saline solution or other physiological buffer suitable for administration to a patient. The particular amount of the compositions of the invention
- 15 that will be administered to the mammal for any particular condition will depend on the clinical condition of the patient, and other factors such as the weight, age, and route of delivery. Such composition can be administered by any suitable route. Alternatively, for treatment purposes, nucleic acids can be administered to the patient using any of the standard vectors and/or gene delivery methods known in the art. Suitable gene delivery systems include, but are not limited to
- 20 liposomes, naked DNA and viral vectors. These compositions can comprise the protein of the invention, and, optionally, one or more other compounds of interest. Indeed, in this embodiment, the present invention find use in drug potentiation applications. This co-administration may be by simultaneous administration or by separate or sequential administrations. All of these components may be either obtained from natural sources or produced by recombinant genetic engineering
- 25 techniques and/or chemical modification.

**Protein of SEQ ID NO:110 (Internal designation Clone 231462\_117-065-1-0-G11-F)**

The cDNA of Clone 231462\_117-065-1-0-G11-F (SEQ ID NO:109) encodes the 386 amino acid long polypeptide, DROCK2, of SEQ ID NO:110 comprising the amino acid sequence:

- MCLLLSCPCHPSAHGQSMWIERTSFVTAYKLPGLRWFEVVHMSQTTISPLENAIETMSTA
- 30 NEKILMMINQYQSDETLPINPLSMLLNGIVDPAVMGGFAKYEKAFTEEYVRDHPEDQDK  
LTHLKDLIAWQIPFLGAGIKIHEKRVSDNLRPFHDMEECFKNLKMKEKEYGVREMPDF

QMSFASQSMPTIPALALSVAGIPGLDEANTSPRLSQFTLQLSDGDKKTLTRKKVNQFFKTM
- 35 LASKSAEEGKQIPDSLSTDL. Accordingly, it will be appreciated that all characteristics and uses of polypeptides of SEQ ID NO:110 described throughout the present application also pertain to the polypeptides encoded by the nucleic acids included in Clone 231462 117-065-1-0-G11-F. In

addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:109 described throughout the present application also pertain to the nucleic acids included in Clone 231462 117-065-1-0-G11-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:109, SEQ ID NO:110, and Clone 231462 117-065-1-0-G11-F.

- 5 Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

DROCK2, the protein of SEQ ID NO:110, is a splicing variant of DOCK2 (EMBL entry Q92608) retaining the last 370 amino acid of DOCK2, while the first sixteen amino acids (MCLLLSCPCHPSAHGQ) represent specific DROCK2 amino acids corresponding to signal  
10 sequence. The resulting isoform is thus lacking the N-terminal sequences of the DOCK2 isoform. However, it retains DOCK2's C-terminal domain comprising a twenty amino acid sequence (LASKSAEEGKQIPDSLSTDL) which has been shown to be involved in protein-protein interactions by interacting with PDZ domain of membrane-associated proteins.

DROCK2 belongs with DOCK2 to the CDM family of signaling proteins which also  
15 comprises the human DOCK180 protein and its homologues, the Ced-5 protein in *Caenorhabditis elegans* and Mbc polypeptide in *Drosophila melanogaster*. These proteins share extensive similarities at the amino acid level, except in their carboxyl-terminal regions that are divergent. CDM proteins have been implicated in polarized extension of the cell surface in their respective organisms. Mbc in *Drosophila* is necessary for myoblast fusion and for migration of epithelial  
20 cells, both of which require reorganization of the cytoskeleton. Ced-5 has also been shown to be involved in the regulation of the cytoskeleton in the nematode, loss of function of which results in defects in engulfing dead cells and in the migration of distal tip cells. Finally, the human DOCK180 protein which was originally identified as one of the major proteins bound to the CrkII adaptator protein, is involved in membrane ruffling and cell migration in nonadherent cells. It has  
25 been shown to transduce signals from the CrkII-p130Cas complex to both the cytoskeleton and JNK pathway by activating the low molecular weight Rac GTPase.

DROCK2, in contrast to DOCK180, which is expressed in all tissues except in peripheral blood cells, is expressed only in circulating blood cells, lymphocytes and macrophages present in organs. Thus the protein is specifically expressed by nonadherent cells. DROCK2 is involved in  
30 blood cell migration and phagocytosis of apoptotic cells by macrophages where it binds to and activates Rac GTPases.

An embodiment of the invention is directed to a composition comprising a DROCK2 polypeptide sequence of SEQ ID NO:110.

A further embodiment of the invention is directed to a composition comprising a DROCK2  
35 polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO:109 encoding a DROCK2 polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a DROCK2 polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a method of screening test substances for modulators of DROCK2 expression comprising the steps of: i) contacting a cell with a  
5 substance to be tested; and ii) comparing DROCK2 expression in the cell after exposure to the test substance to that of an untreated control cell.

In one embodiment, the present invention provides a method of producing a recombinant protein capable of effectively increasing Rac GTPase activity. The protein of the invention can be produced in host cells that have been transfected with an appropriate expression vector comprising  
10 a nucleic acid sequence coding for the protein of the invention. Introduction into a host cell of such expression vector for DROCK2 can be performed in a variety of ways, including but not limited to calcium or lithium chloride treatment, electroporation, or lipofection. Any of a wide variety of expression systems can be used to provide the recombinant proteins. Suitable expression vehicles include, but are not limited to plasmids, viral particles or baculovirus for insect cells. The  
15 expression vehicle can be integrated into the host cell genome. Optionally, an inducible expression vector can be used to achieve tight controlled expression of the gene in the host cell.

Another embodiment the present invention provides methods to purify from cellular extracts proteins harboring one or more PDZ domain, preferably proteins belonging to the MAGUK (Membrane Associated and Guanylate Kinase) family, more preferably proteins selected  
20 from the group consisting of DLG, syntenin or PSD95 proteins, by using the present protein, preferably its C-terminal twenty amino acid sequence to copurify those proteins. Methods to affinity purify proteins are well known for those skilled in the art. For example, the PDZ-containing proteins can be purified on an affinity column or on solid support like beads using the polypeptides of the invention. The protein to be purified using the present method can be derived  
25 from any source, e.g. protein expressed in vitro using an invertebrate, yeast or bacterial heterologous expression system.

Another embodiment of the invention is directed to a method to increase phagocytosis of apoptotic cells. Preferably, this method is applied in vivo to an individual. The method comprises the steps of: i) removing a sample of monocytes, ii) introducing a polynucleotide encoding a  
30 DROCK-2 polypeptide or fragment thereof ex vivo to those cells, and iii) reinjecting the recombinant cells into an individual. Using such a method in combination with anticancer or antiviral therapies would be of particular interest for the rapid elimination of apoptotic cancer or infected cells.

An embodiment of the invention provides for a method of screening test substances for  
35 modulators of DROCK-2 expression. This method comprises the steps of: i) contacting a cell with a test substance; and ii) comparing DROCK-2 expression in the cell after exposure to the test substance to that of an unexposed control cell. DROCK-2 expression is determined by methods

common to the art or included herein, by detecting DROCK-2 polynucleotides or polypeptides. An example of this method comprises the steps of: i) culturing two equivalent cell samples; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures at a specified time; iv) purifying the mRNA from each sample of cells; v) comparing the level of

5 DROCK-2 mRNA in each sample by Northern blot, RTPCR, or another method common to the art. The invention provides for design and use of specific polynucleotide probes and primers, as discussed herein. An additional example comprises the steps of: i) having two equivalent cultures of cells; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures; iv) purifying the protein from each sample of cells; v) comparing the level of DROCK-2

10 polypeptides in each sample by Western blot, immunohistochemistry, or another method common to the art. The invention provides for design and use of specific antibodies and antibody fragments, as discussed herein. Substances that increase DROCK-2 expression (agonists) may be used to increase cytoskeletal remodeling and Rac activation. Substances that decrease DROCK-2 expression (antagonists) may be used to inhibit cytoskeletal remodeling and Rac activation.

15 Methods utilizing DROCK-2 agonists and antagonists are included herein.

A preferred embodiment of the invention provides a method of screening for test substances that bind DROCK-2 polypeptides. This method comprises the steps of: i) contacting a test substance with a DROCK-2 polypeptide or fragment thereof under conditions that allow binding; and ii) detecting the binding of the test substance by methods common to the art (e.g.,

20 competitive antibody-based methods such as coimmunoprecipitation and Western blotting). Included in this method are test substances that are conjugated to an antibody, antibody fragment, cell-type specific ligand or a portion thereof.

A further preferred embodiment of the invention provides a method of screening test substances that bind to DROCK-2 for antagonists of DROCK-2 activity. This method comprises

25 the steps of: i) contacting a cell with a test substance; and ii) comparing DROCK-2 biological activity after exposure to the test substance to that of an unexposed control cell. Detection of DROCK-2 biological activity may be detected by detecting activity of Rac GTPase. An example of an assay detecting Rac activity comprises the steps of: exposing Rac GTPase to radiolabeled GTP and detecting the amount of hydrolysis by detecting the amount of free, radiolabeled

30 phosphate.

A further embodiment of the present invention is also directed to a method to reduce the elimination rate of apoptotic cells in a patient subjected to an antiapoptotic treatment, such method comprising removing a sample of the monocytes/macrophages of said patient, inhibiting or reducing the expression of the present protein in the isolated cells ex vivo, and reinjecting the

35 modified cells to the patient. Methods to inhibit the expression of a given gene in a cell are well known in the art, e.g. using antisense or ribozyme strategies, any of which can be used in the present method. Alternatively, reduced phagocytosis of apoptotic cells in said patient can be

achieved by interfering with the normal activity of the present protein. In such a method, the isolated monocytes are transfected *ex vivo* with a DROCK2 fragment corresponding to the last twenty carboxy-terminal amino acid prior to reinjection into the patient. Because reducing phagocytosis of apoptotic cells concomitantly with the administration of the antiapoptotic agent

5 would help maintaining more dying cells alive and therefore available for the action of the antiapoptotic agent, such method would be of particular interest to increase the treatment efficiency of diseases associated with abnormal cell apoptosis, including but not limited to neurodegenerative disorders.

A preferred embodiment provides a method of preventing and treating invasive neoplasms that  
10 require cytoskeletal remodeling (e.g., for extravasation). This method comprises the step of contacting an antagonist of DROCK-2 expression or activity with a cell. Preferred cells include nonadherent cells. Further preferred cells include lymphocytes and macrophages. Preferably, the DROCK-2 antagonist is delivered to a specific cell type, for example, by conjugating the antagonist to a cell-type specific targeting moiety (e.g., a ligand or antibody fragment). DROCK-2  
15 antagonists in a physiologically acceptable solution may be delivered by methods common to the art, such as orally or parenterally. This method is useful for prevention and treatment of leukemias and other invasive neoplasms.

**Protein of SEQ ID NO:112 (Internal designation Clone 500723589\_205-34-3-0-G4-F)**

The cDNA of clone 500723589\_205-34-3-0-G4-F (SEQ ID NO:111) encodes Novel 17 beta-  
20 hydroxysteroid dehydrogenase type 2 (NBHSD2) of SEQ ID NO:112, comprising the amino acid sequence:  
MSTFFSDTAWICLAVPTVLCGTVFCKYKKSSGQLWSWMVCLAGLCAVCLLILSPFWGLIL  
FSVSCFLMYTYLSGQELLPVDQKAVLVTGGDCGLGHALCKYLDELGFTVFAGVLNENGP  
GAELRRTCSPRLSVLQMDITKPVIKDAYSKVAAMLQDRGLWAVINNAGVLGFPTDGE  
25 LLLMTDYKQCMVNFVGTVEVTKTFLPLLRKSKGRLVNVSSMGGGAPVERLASYGSSKA  
AVTMFSSVMRLELSKWGIKVASIQPGGFLTNIAGTSDKWEKLEKDILDHLP AEVQEDYCQ  
DYILAQRNLLLLINSLASKDFSPVLRDIQHAILAKSPFAYYTPGKGAYLWICLAHYLP IGIYD  
YFAKRHFGQDKPMRPRALRMPNYKKKAP. Accordingly, it will be appreciated that all characteristics and uses of the polypeptides of SEQ ID NO:112 described throughout the present  
30 application also pertain to the polypeptides encoded by the nucleic acids included in Clone 500723589\_205-34-3-0-G4-F. In addition, it will be appreciated that all characteristics and uses of the polynucleotides of SEQ ID NO:111 described throughout the present application also pertain to the nucleic acids included in Clone 500723589\_205-34-3-0-G4-F. A preferred embodiment of the invention is directed toward the compositions of SEQ ID NO:111, SEQ ID NO:112, and clone  
35 500723589\_205-34-3-0-G4-F. Also preferred are polypeptide fragments having a biological activity as described herein and the polynucleotides encoding the fragments.

The protein of SEQ ID NO:112 is a polymorphic variant of the sequence of 17 beta

estradiol dehydrogenase (swissprot accession number P37059). Like 17 beta-hydroxysteroid dehydrogenase type 2, the protein of the invention displays a short chain dehydrogenase domain (PF00106) spanning from positions 83 to 268, a ferredoxin domain (PS00197) spanning from positions 40 to 48 and an ADH-short domain spanning from positions 219 to 247.

- 5        Novel 17 beta-hydroxysteroid dehydrogenase type 2 (NBHSD2) is an enzyme of the 17 beta-hydroxysteroid dehydrogenase (17 beta-HSD) gene family. The 17 beta-hydroxysteroid dehydrogenases are pivotal in controlling the biological potency of steroid hormones by catalyzing oxidation or reduction at position 17.

- 10        17 Beta-hydroxysteroid dehydrogenases catalyze the interconversion between high-activity 17beta-hydroxysteroids and low-activity 17-ketosteroids. Because both estrogens and androgens have the highest affinity towards their receptors in the 17 beta-hydroxy form, the 17 beta-HSD enzymes regulate the biological activity of sex hormones. Several 17beta-HSD may metabolize further substrates including alcohols, bile acids, fatty acids and retinol. The activities of 17 beta HSDs are essential for gonadal sex steroid biosynthesis and they are also involved in the
- 15        modulation of steroid hormone action in peripheral tissues. This family of steroidogenic enzymes constitutes an interesting target in the control of the concentration of estrogens and androgens since this family is involved in the formation and inactivation of sex steroids.

- 20        NBHSD2 catalyzes the oxidative reaction or the inactivation of sex steroids thereby reducing the exposure of tissues to the action of sex steroids. NBHSD2 preferentially catalyzes the oxidation of estradiol (E(2)) to inactive estrogen, estrone (E(1)), testosterone to 4-dione, dihydrotestosterone (DHT), 20alpha-dihydroprogesterone (20alpha-DHP), and androst-5-ene-3, 17-diol (5-diol) to DHEA with NAD<sup>+</sup> as the coenzyme. Therefore, NBHSD2 is involved in the regulation of clearance and/or metabolism of sex steroids.

- 25        Local formation of sex steroids plays a major role in both normal and neoplastic hormone-sensitive tissues. 40% of all cancers, namely, breast, prostate, ovarian and uterine cancers, are sex steroid-sensitive and are thus prime candidates for approaches based upon the control of synthesis of active steroids in peripheral target tissues. Thus, the rate of formation of each sex steroid depends upon the activity of the specific androgen- and estrogen-synthesizing enzymes in each cell of each tissue. Local hormone metabolism plays a key role in determining tissue responsiveness to
- 30        oestrogen. High capacity for inactivation of oestrogens is associated with the presence of 17beta-HSD isozymes in epithelial cells. By inactivating oestrogens, NBHSD2 plays a role in cancers, especially hormone-dependent cancers such as those stimulated by androgens or estrogens, for example, colon, breast, prostate, ovarian and uterine cancer. In the colon, NBHSD2 plays a role as attenuator of estradiol E2 bioavailability (estradiol (E2) stimulates the growth of colonic cancer
- 35        cell lines), and possibly as modulators of colonic cell proliferation in the pathogenesis of colon cancer.

Also, bioavailability of estradiol, one of the most potent human sex steroid hormones of

placental origin, is essential to the maintenance of pregnancy, the timing of parturition, the maturation of many fetal organs, and the preparation of the maternal reproductive system.

Several inhibitors of the functions of NBHSD2 have been characterized. These include:

lindane which induces oxidative stress, progestins (promegestone, nomegestrol acetate, medrogestone) and tibolone and its metabolite which will provide a new possibility in the treatment of breast cancer, chalcones (naringenin chalcone and 4-hydroxychalcone), steroidal spirolactones inhibitors, isoflavones which have been suggested to be anticarcinogenic, propylthiouracil (PTU) which is an anti-thyroid drug. Such inhibitors are useful tools to regulate the level of active estrogens, androgens and progesterone and can exert cancer-preventive effects.

Alternatively, retinoic acids stimulate the expression of NBHSD2 and may be involved in modulation of in situ estrogen metabolism in both normal and neoplastic human endometrium.

An embodiment of the invention is directed to a composition comprising a NBHSD2 polypeptide sequence of SEQ ID NO:112.

A further embodiment of the invention is directed to a composition comprising a NBHSD2 polypeptide fragment having biological activity.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence of SEQ ID NO:111 encoding a NBHSD2 polypeptide.

A further embodiment of the invention is directed to a composition comprising a polynucleotide sequence encoding a NBHSD2 polypeptide fragment having biological activity.

An embodiment of the invention provides for a method of screening test substances for modulators of NBHSD2 expression. This method comprises the steps of: i) contacting a cell with a test substance; and ii) comparing NBHSD2 expression in the cell after exposure to the test substance to that of an unexposed control cell. NBHSD2 expression is determined by methods common to the art or included herein, by detecting NBHSD2 polynucleotides or polypeptides. An example of this method comprises the steps of: i) culturing two equivalent cell samples; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures at a specified time; iv) purifying the mRNA from each sample of cells; v) comparing the level of NBHSD2 mRNA in each sample by Northern blot, RTPCR, or another method common to the art. The invention provides for design and use of specific polynucleotide probes and primers, as discussed herein. An additional example comprises the steps of: i) having two equivalent cultures of cells; ii) adding a test substance to one of the cultures and not the other; iii) harvesting both cultures; iv) purifying the protein from each sample of cells; v) comparing the level of NBHSD2 polypeptides in each sample by Western blot, immunohistochemistry, or another method common to the art. The invention provides for design and use of specific antibodies and antibody fragments, as discussed herein.

Agents which modulate the expression or activity of the NBHSD2 of the subject invention include, but are not limited to, antisense oligonucleotides, ribozymes, drugs, and antibodies. These

agents may be made and used according to methods well known in the art. Also, the protein of the invention, or biologically active fragments thereof, may be used in screening assays for therapeutic compounds. A variety of drug screening techniques may be employed. In this aspect of the invention, the protein or biologically active fragment thereof, may be free in solution, affixed to a solid support, recombinantly expressed on, or chemically attached to, a cell surface, or located intracellularly. The formation of binding complexes, between the protein of the invention, or biologically active fragments thereof, and the compound being tested, may then be measured. Another technique for drug screening which may be used provides for high throughput screening of compounds having suitable binding affinity to the protein of the invention as described in published PCT application WO84/03564, and incorporated herein by reference in its entirety.

Another embodiment of the subject invention provides compositions and methods of selectively modulating the activity of the protein of the invention. Modulation of the NBHSD2 activity would allow for the successful treatment and/or management of diseases or biochemical abnormalities associated with the NBHSD2. Antagonists, able to reduce or inhibit the expression or the activity of the protein of the invention, would be useful in the treatment of diseases associated with decreased estradiol and testosterone biosynthesis. For example, estradiol deficiency is an important pathogenetic factor in female osteoporosis. Also, antagonists of NBHSD2 provide methods of treating diseases including, and not limited to, cancers, especially hormone-dependent cancers such as those stimulated by androgens or estrogens. Androgen-sensitive diseases, i.e. diseases whose onset or progress is aided by androgenic activity, are known, included but are not limited to prostate cancer, benign prostatic hyperplasia; acne, seborrhea, hirsutism, androgenic alopecia, precocious puberty, adrenal hyperplasia and polycystic ovarian syndrome. Estrogen sensitive diseases, i.e. diseases whose onset or progress is aided by estrogenic activity, included but are not limited to breast cancer, endometriosis, leiomyoma, and precocious puberty.

Alternatively, the subject invention provides methods of treating diseases or disorders associated with decreased levels of the protein of the NBHSD2. Thus, agonists of NBHSD2 provide methods for treating diseases with increases in estradiol and testosterone levels.

In one embodiment, the subject method utilizes eukaryotic or prokaryotic host cells which are stably transformed with recombinant nucleic acids expressing the NBHSD2 polypeptide or biologically active fragments thereof. The transformed cells may be viable or fixed. Drugs or compounds which are candidates for the modulation of the NBHSD2, or biologically active fragments thereof, are screened against such transformed cells in binding assays well known to those skilled in the art. Alternatively, assays such as those taught in Geysen H. N., WO Application 84/03564, published on Sep. 13, 1984, and incorporated herein by reference in its entirety, may be used to screen for peptide compounds which demonstrate binding affinity for, or the ability to modulate, the NBHSD2, or biologically active fragments thereof. In another

embodiment, competitive drug screening assays using neutralizing antibodies specifically compete with a test compound for binding to the NBHSD2 protein of the invention, or biologically active fragments thereof.

Agents which stimulate or inhibit the activity of the protein of the invention include but are not limited to agonist and antagonist drugs respectively. These drugs can be obtained using any of a variety of drug screening techniques as discussed above.

Antagonists of the NBHSD2 polypeptide encoded by SEQ ID NO:112 include agents which decrease the levels of expressed mRNA encoding the protein of SEQ ID NO:112. These include, but are not limited to, RNAi, one or more ribozymes capable of digesting the protein of the invention mRNA, or antisense oligonucleotides capable of hybridizing to mRNA encoding the NBHSD2 polypeptide of SEQ ID NO:112. Antisense oligonucleotides can be administered as DNA, as DNA entrapped in proteoliposomes containing viral envelope receptor proteins [Kanoda, Y. *et al.* (1989) *Science* 243: 375, which disclosure is hereby incorporated by reference in its entirety] or as part of a vector which can be expressed in the target cell and provide antisense DNA or RNA. Vectors which are expressed in particular cell types are known in the art. Alternatively, the DNA can be injected along with a carrier. A carrier can be a protein such as a cytokine, for example interleukin 2, or polylysine-glycoprotein carriers. Carrier proteins, vectors, and methods of making and using polylysine carrier systems are known in the art. Alternatively, nucleic acid encoding antisense molecules may be coated onto gold beads and introduced into the skin with, for example, a gene gun [Ulmer, J.B. *et al.* (1993) *Science* 259:1745, which disclosure is hereby incorporated by reference in its entirety].

Antibodies, or other polypeptides, capable of reducing or inhibiting the activity of NBHSD2 may be provided as in isolated and substantially purified form. Alternatively, antibodies or other polypeptides capable of inhibiting or reducing the activity of the protein of the invention, may be recombinantly expressed in the target cell to provide a modulating effect. In addition, compounds which inhibit or reduce the activity of the protein of the subject invention may be incorporated into biodegradable polymers being implanted in the vicinity of where drug delivery is desired. For example, biodegradable polymers containing antagonists/agonists may be implanted to slowly release the compounds systemically. Biodegradable polymers, and their use, are known to those of skill in the art (see, for example, Brem *et al.*, *J. Neurosurg.* 74:441-446(1991) which disclosure is hereby incorporated by reference in its entirety).

In one embodiment, methods of increasing the levels of NBHSD2 in tissues or cell types may be practiced by utilizing nucleic acids encoding the protein of the subject invention, or biologically active fragments thereof, to introduce biologically active polypeptide into targeted cell types. Vectors useful in such methods are known to those skilled in the art as are methods of introducing such nucleic acids into target tissues. Preferred expression vectors include viral vectors, especially adenoviral and lentiviral vectors. For example, one of the methods described in

Mulligan (Mulligan, Science, 260:926-32 (1993)), which disclosure is hereby incorporated by reference in its entirety, can be used.

In another embodiment, the invention provides methods and compositions for detecting the level of expression of the mRNA of the protein of the invention. Quantification of mRNA levels of the NBHSD2 protein of the invention may be useful for the diagnosis or prognosis of diseases associated with an altered expression of the protein of the invention. Assays for the detection and quantification of the mRNA of the protein of the invention are well known in the art (see, for example, Maniatis, Fitch and Sambrook, Molecular Cloning; A Laboratory Manual (1982), or Current Protocols in Molecular Biology, Ausubel, F.M. *et al.* (Eds), Wiley & Sons, Inc.).

Polynucleotides probes or primers for the detection of NBHSD2 cDNA can be designed from the cDNA of SEQ ID NO:111. Methods for designing probes and primers are known in the art. In another embodiment, the subject invention provides diagnostic kits for the detection of NBHSD2 cDNA in cells. The kit comprises a package having one or more containers of oligonucleotide primers for detection of NBHSD2 cDNA in PCR assays or one or more containers of polynucleotide probes for the detection of NBHSD2 cDNA by in situ hybridization or Northern analysis. Kits may, optionally, include containers of various reagents used in various hybridization assays. The kit may also, optionally, contain one or more of the following items: polymerization enzymes, buffers, instructions, controls, or detection labels. Kits may also, optionally, include containers of reagents mixed together in suitable proportions for performing the hybridization assay methods in accordance with the invention. Reagent containers preferably contain reagents in unit quantities that obviate measuring steps when performing the subject methods.

In another embodiment, the invention relates to methods and compositions for detecting and quantifying the level of the protein of the invention present in a particular biological sample. These methods are useful for the diagnosis or prognosis of diseases associated with an altered levels of the protein of the invention. Diagnostic assays to detect the protein of the invention may comprise a biopsy, in situ assay of cells from organ or tissue sections, or an aspirate of cells from a tumor or normal tissue. In addition, assays may be conducted upon cellular extracts from organs, tissues, cells, urine, or serum or blood or any other body fluid or extract.

Assays for the quantification of the NBHSD2 polypeptide of SEQ ID NO:112 may be performed according to methods well known in the art. Typically, these assays comprise contacting the sample with a ligand of the protein of the invention or an antibody (polyclonal or monoclonal) which recognizes the protein of the invention or a fragment thereof, and detecting the complex formed between the protein of the invention present in the sample and the ligand or antibody. Fragments of the ligands and antibodies may also be used in the binding assays, provided these fragments are capable of specifically interacting with the NBHSD2 of the subject invention. Further, the ligands and antibodies which bind to the NBHSD2 of the invention may be labeled according to methods known in the art. Labels which are useful in the subject invention

include, but are not limited to, enzymes labels, radioisotopic labels, paramagnetic labels, and chemiluminescent labels. Typical techniques are described by Kennedy, J. H., *et al.* (1976) *Clin. Chim. Acta* 70:1-31; and Schurs, A. H. *et al.* (1977) *Clin. Chim. Acta* 81: 1-40 which disclosure is hereby incorporated by reference in its entirety).

- 5 In another embodiment, the invention relates to compositions and methods using the proteins of the invention or fragment thereof to screen for compounds that bind an NBHSD2 polypeptide or fragment thereof. In a preferred embodiment, the proteins of the invention or fragment thereof may be used to identify and/or quantify substrates using any techniques known to those skilled in the art. To find substrates, the proteins of the invention, or fragment thereof, or derivative thereof, may be used for screening libraries of compounds in any of a variety of drug screening techniques. The fragment employed in such screening may be free in solution, affixed to a solid support, borne on a cell surface, or located intracellularly. The formation of binding complexes, between the proteins of the invention, or fragment thereof, or derivative thereof, and the agent being tested, may be measured by methods well known to those skilled in the art, like, but not limited to, the BIAcore (Uppsala, Sweden). Antagonists or inhibitors of the proteins of the invention may be produced using methods which are generally known in the art, including the screening of libraries of pharmaceutical agents to identify those which specifically bind the protein of the invention. Another technique for drug screening which may be used provides for high throughput screening of compounds having suitable binding affinity to the protein of the invention.
- 20 In another embodiment, the present invention includes the use of NBHSD2 polypeptides, or fragments having a desired biological activity to treat or ameliorate a condition in an individual. For example, the condition may be deficiency of the sex steroid biosynthesis such as hormone-dependent disorders, or an abnormality in any of the functions of the sex steroid metabolism. In such embodiments, AN NBHSD2 polypeptide, or a fragment thereof, is administered to an individual in whom it is desired to increase or decrease any of the activities of NBHSD2 polypeptides. A NBHSD2 polypeptide or fragment thereof may be administered directly to the individual or, alternatively, a nucleic acid encoding a NBHSD2 polypeptide or a fragment thereof may be administered to the individual. Alternatively, an agent which increases the activity of NBHSD2 polypeptides may be administered to the individual. Such agents may be identified by contacting a NBHSD2 polypeptide or a cell or preparation containing NBHSD2 polypeptides with a test agent and assaying whether the test agent increases the activity of the protein. For example, the test agent may be a chemical compound or a polypeptide or peptide. Alternatively, the activity of NBHSD2 polypeptides may be decreased by administering an agent which interferes with such activity to an individual. Agents which interfere with the activity of NBHSD2 polypeptides may be identified by contacting A NBHSD2 polypeptide or a cell or preparation containing NBHSD2 polypeptides with a test agent and assaying whether the test agent decreases the activity of the protein. . Decreasing the activity of NHBSD2 would be useful for the successful treatment and/or
- 35

management of diseases or biochemical abnormalities associated with decrease of oestradiol. For example, the agent may be a chemical compound, a polypeptide or peptide, an antibody, or a nucleic acid such as an antisense nucleic acid or a triple helix-forming nucleic acid. Another embodiment of the invention relates to composition and methods using polynucleotide sequences encoding the protein of the invention or fragment thereof to establish transgenic model animals (D. *melanogaster*, *M. musculus*), by any method familiar to those skilled in the art. By modulating *in vivo* the expression of the transgene with drugs or modifier genes (activator or suppressor genes), animal models can be developed that mimic human hormone-dependent disorders such as cancers. These animal models would thus allow the identification of potential therapeutic agents for treatment of the disorders. In addition, recombinant cell lines derived from these transgenic animals may be used for similar approaches *ex vivo*.

In another embodiment, an array of oligonucleotides probes comprising the nucleotide sequence of SEQ ID NO:111 or fragments thereof can be constructed to conduct efficient screening of e.g., genetic mutations or deletion. The microarray can be used to monitor the expression level of large numbers of genes simultaneously and to identify genetic variants, mutations, and polymorphisms. This information may be used to determine gene function, to understand the genetic basis of a disorder, to diagnose a disorder, and to develop and monitor the activities of therapeutic agents (see for example: Chee, M. et al., Science, 274:610-614 (1996) which disclosure is hereby incorporated by reference in its entirety). For example, deletion of genes NBHSD2 locus is a frequent target of deletion in human hepatocellular carcinoma.

#### Uses of antibodies

Antibodies of the present invention have uses that include, but are not limited to, methods known in the art to purify, detect, and target the polypeptides of the present invention including both *in vitro* and *in vivo* diagnostic and therapeutic methods. An example of such use using immunoaffinity chromatography is given below. The antibodies of the present invention may be used either alone or in combination with other compositions. For example, the antibodies have use in immunoassays for qualitatively and quantitatively measuring levels of antigen-bearing substances, including the polypeptides of the present invention, in biological samples (See, e.g., Harlow *et al.*, 1988). (Incorporated by reference in the entirety). The antibodies may also be used in therapeutic compositions for killing cells expressing the protein or reducing the levels of the protein in the body.

The invention further relates to antibodies that act as agonists or antagonists of the polypeptides of the present invention. For example, the present invention includes antibodies that disrupt the receptor/ligand interactions with the polypeptides of the invention either partially or fully. Included are both receptor-specific antibodies and ligand-specific antibodies. Included are receptor-specific antibodies, which do not prevent ligand binding but prevent receptor activation.

Receptor activation (i.e., signaling) may be determined by techniques described herein or otherwise known in the art. Also include are receptor-specific antibodies which both prevent ligand binding and receptor activation. Likewise, included are neutralizing antibodies that bind the ligand and prevent binding of the ligand to the receptor, as well as antibodies that bind the ligand, thereby preventing receptor activation, but do not prevent the ligand from binding the receptor. Further included are antibodies that activate the receptor. These antibodies may act as agonists for either all or less than all of the biological activities affected by ligand-mediated receptor activation. The antibodies may be specified as agonists or antagonists for biological activities comprising specific activities disclosed herein. The above antibody agonists can be made using methods known in the art. *See e.g.*, WO 96/40281; US Patent 5,811,097; Deng *et al.*, (1998) Blood. 92(6):1981-1988; Chen *et al.*, (1998), Cancer Res. 58(16):3668-3678; Harrop *et al.*, (1998), J. Immunol. 161(4):1786-1794; Zhu, *et al.* (1998), Cancer Res. 58(15):3209-3214; Yoon, *et al.* (1998), J. Immunol. 160(7):3170-3179; Prat *et al.*, (1998), J. Cell. Sci. 111(Pt2):237-247; Pitard *et al.*, (1997), J. Immunol. Methods. 205(2):177-190; Liautard *et al.*, (1997), Cytokine. 9(4):233-241; Carlson *et al.*, (1997), J. Biol. Chem. 272(17):11295-11301; Taryman, *et al.*, (1995), Neuron. 14(4):755-762; Muller *et al.*, (1998), Structure. 6(9):1153-1167; Bartunek *et al.*, (1996), Cytokine. 8(1):14-20 (said references incorporated by reference in their entireties).

As discussed above, antibodies of the polypeptides of the invention can, in turn, be utilized to generate anti-idiotypic antibodies that "mimic" polypeptides of the invention using techniques well known to those skilled in the art [*See, e.g.* Greenspan and Bona (1989), FASEB J. 7(5):437-444 and Nissinoff, (1991), J. Immunol. 147(8): 2429-2438, which disclosures are hereby incorporated by reference in their entireties]. For example, antibodies which bind to and competitively inhibit polypeptide multimerization or binding of a polypeptide of the invention to ligand can be used to generate anti-idiotypes that "mimic" the polypeptide multimerization or binding domain and, as a consequence, bind to and neutralize polypeptide or its ligand. Such neutralization anti-idiotypic antibodies can be used to bind a polypeptide of the invention or to bind its ligands/receptors, and thereby block its biological activity.

#### Immunoaffinity Chromatography

Antibodies prepared as described herein are coupled to a support. Preferably, the antibodies are monoclonal antibodies, but polyclonal antibodies may also be used. The support may be any of those typically employed in immunoaffinity chromatography, including Sepharose CL-4B (Pharmacia, Piscataway, NJ), Sepharose CL-2B (Pharmacia, Piscataway, NJ), Affi-gel 10 (Biorad, Richmond, CA), or glass beads.

The antibodies may be coupled to the support using any of the coupling reagents typically used in immunoaffinity chromatography, including cyanogen bromide. After coupling the antibody to the support, the support is contacted with a sample which contains a target polypeptide

whose isolation, purification or enrichment is desired. The target polypeptide may be a polypeptide selected from the group consisting of polypeptide sequences of the Sequence Listing, those encoded by the clone inserts of the deposited clone pool, variants and fragments thereof, or a fusion protein comprising said selected polypeptide or a fragment thereof.

- 5 Preferably, the sample is placed in contact with the support for a sufficient amount of time and under appropriate conditions to allow at least 50% of the target polypeptide to specifically bind to the antibody coupled to the support.

Thereafter, the support is washed with an appropriate wash solution to remove polypeptides which have non-specifically adhered to the support. The wash solution may be any  
 10 of those typically employed in immunoaffinity chromatography, including PBS, Tris-lithium chloride buffer (0.1M lysine base and 0.5M lithium chloride, pH 8.0), Tris-hydrochloride buffer (0.05M Tris-hydrochloride, pH 8.0), or Tris/Triton/NaCl buffer (50mM Tris.cl, pH 8.0 or 9.0, 0.1% Triton X-100, and 0.5MNaCl).

After washing, the specifically bound target polypeptide is eluted from the support using  
 15 the high pH or low pH elution solutions typically employed in immunoaffinity chromatography. In particular, the elution solutions may contain an eluant such as triethanolamine, diethylamine, calcium chloride, sodium thiocyanate, potassium bromide, acetic acid, or glycine. In some embodiments, the elution solution may also contain a detergent such as Triton X-100 or octyl-beta-D-glucoside.

20

#### **EXPRESSION OF GENSET GENE PRODUCTS**

##### **Evaluation of Expression Levels and Patterns of GENSET polypeptide-encoding mRNAs**

The spatial and temporal expression patterns of GENSET polypeptide-encoding mRNAs, as well as their expression levels, may be determined as follows.

- 25 Expression levels and patterns of GENSET polypeptide-encoding mRNAs may be analyzed by solution hybridization with long probes as described in International Patent Application No. WO 97/05277, the entire contents of which are hereby incorporated by reference. Briefly, a GENSET polynucleotide, or fragment thereof, corresponding to the gene encoding the mRNA to be characterized is inserted at a cloning site immediately downstream of a bacteriophage  
 30 (T3, T7 or SP6) RNA polymerase promoter to produce antisense RNA. Preferably, the GENSET polynucleotide is at least a 100 nucleotides in length. The plasmid is linearized and transcribed in the presence of ribonucleotides comprising modified ribonucleotides (i.e. biotin-UTP and DIG-UTP). An excess of this doubly labeled RNA is hybridized in solution with mRNA isolated from cells or tissues of interest. The hybridizations are performed under standard stringent conditions  
 35 (40-50°C for 16 hours in an 80% formamide, 0.4 M NaCl buffer, pH 7-8). The unhybridized probe is removed by digestion with ribonucleases specific for single-stranded RNA (i.e. RNases CL3, T1, Phy M, U2 or A). The presence of the biotin-UTP modification enables capture of the hybrid on a

microtitration plate coated with streptavidin. The presence of the DIG modification enables the hybrid to be detected and quantified by ELISA using an anti-DIG antibody coupled to alkaline phosphatase.

The GENSET polypeptide-encoding cDNAs, or fragments thereof, may also be tagged with nucleotide sequences for the serial analysis of gene expression (SAGE) as disclosed in UK Patent Application No. 2 305 241 A, the entire contents of which are incorporated by reference. In this method, cDNAs are prepared from a cell, tissue, organism or other source of nucleic acid for which it is desired to determine gene expression patterns. The resulting cDNAs are separated into two pools. The cDNAs in each pool are cleaved with a first restriction endonuclease, called an "anchoring enzyme," having a recognition site which is likely to be present at least once in most cDNAs. The fragments which contain the 5' or 3' most region of the cleaved cDNA are isolated by binding to a capture medium such as streptavidin coated beads. A first oligonucleotide linker having a first sequence for hybridization of an amplification primer and an internal restriction site for a "tagging endonuclease" is ligated to the digested cDNAs in the first pool. Digestion with the second endonuclease produces short "tag" fragments from the cDNAs. A second oligonucleotide having a second sequence for hybridization of an amplification primer and an internal restriction site is ligated to the digested cDNAs in the second pool. The cDNA fragments in the second pool are also digested with the "tagging endonuclease" to generate short "tag" fragments derived from the cDNAs in the second pool. The "tags" resulting from digestion of the first and second pools with the anchoring enzyme and the tagging endonuclease are ligated to one another to produce "ditags." In some embodiments, the ditags are concatamerized to produce ligation products containing from 2 to 200 ditags. The tag sequences are then determined and compared to the sequences of the GENSET polypeptide-encoding cDNAs to determine which genes are expressed in the cell, tissue, organism, or other source of nucleic acids from which the tags were derived. In this way, the expression pattern of a GENSET polypeptide-encoding gene in the cell, tissue, organism, or other source of nucleic acids is obtained.

Quantitative analysis of GENSET gene expression may also be performed using arrays. For example, quantitative analysis of gene expression may be performed with GENSET polynucleotides, or fragments thereof in a complementary DNA microarray as described by Schena *et al.* (1995) *Science* 270:467-470 and Schena *et al.* (1996), *Proc Natl Acad Sci U S A*, 93(20):10614-10619 which disclosures are hereby incorporated by reference in their entireties. GENSET polypeptide-encoding cDNAs or fragments thereof are amplified by PCR and arrayed from 96-well microtiter plates onto silylated microscope slides using high-speed robotics. Printed arrays are incubated in a humid chamber to allow rehydration of the array elements and rinsed, once in 0.2% SDS for 1 min, twice in water for 1 min and once for 5 min in sodium borohydride solution. The arrays are submerged in water for 2 min at 95°C, transferred into 0.2% SDS for 1 min, rinsed twice with water, air dried and stored in the dark at 25°C. Cell or tissue mRNA is

isolated or commercially obtained and probes are prepared by a single round of reverse transcription. Probes are hybridized to 1 cm<sup>2</sup> microarrays under a 14 x 14 mm glass coverslip for 6-12 hours at 60°C. Arrays are washed for 5 min at 25°C in low stringency wash buffer (1X SSC/0.2% SDS), then for 10 min at room temperature in high stringency wash buffer (0.1X  
 5 SSC/0.2% SDS). Arrays are scanned in 0.1X SSC using a fluorescence laser scanning device fitted with a custom filter set. Accurate differential expression measurements are obtained by taking the average of the ratios of two independent hybridizations.

Quantitative analysis of the expression of genes may also be performed with GENSET polypeptide-encoding cDNAs or fragments thereof in complementary DNA arrays as described by  
 10 Pietu *et al.*, (1996) Genome Research 6:492-503, which disclosure is hereby incorporated by reference in its entirety. The GENSET polynucleotides of the invention or fragments thereof are PCR amplified and spotted on membranes. Then, mRNAs originating from various tissues or cells are labeled with radioactive nucleotides. After hybridization and washing in controlled conditions, the hybridized mRNAs are detected by phospho-imaging or autoradiography. Duplicate  
 15 experiments are performed and a quantitative analysis of differentially expressed mRNAs is then performed.

Alternatively, expression analysis of GENSET genes can be done through high density nucleotide arrays as described by Lockhart *et al.*, (1996) Nature Biotechnology 14: 1675-1680 and Sosnowski, *et al.*, (1997) Proc Natl Acad Sci U S A 94:1119-1123, which disclosures are hereby  
 20 incorporated by reference in their entireties. Oligonucleotides of 15-50 nucleotides corresponding to sequences of a GENSET polynucleotide or fragments thereof are synthesized directly on the chip (Lockhart *et al.*, supra) or synthesized and then addressed to the chip (Sosnowski *et al.*, supra). Preferably, the oligonucleotides are about 20 nucleotides in length. cDNA probes labeled with an appropriate compound, such as biotin, digoxigenin or fluorescent dye, are synthesized  
 25 from the appropriate mRNA population and then randomly fragmented to an average size of 50 to 100 nucleotides. The said probes are then hybridized to the chip. After washing as described in Lockhart *et al.*, (supra) and application of different electric fields (Sosnowsky *et al.*, supra), the dyes or labeling compounds are detected and quantified. Duplicate hybridizations are performed. Comparative analysis of the intensity of the signal originating from cDNA probes on the same  
 30 target oligonucleotide in different cDNA samples indicates a differential expression of the GENSET polypeptide-encoding mRNA.

#### **Uses of GENSET gene expression data**

Once the expression levels and patterns of a GENSET polypeptide-encoding mRNA has been determined using any technique known to those skilled in the art, in particular those described  
 35 in the section entitled "Evaluation of Expression Levels and Patterns of GENSET polypeptide-encoding mRNAs", or using the instant disclosure, these information may be used to design GENSET gene specific markers for detection, identification, screening and diagnosis purposes as

well as to design DNA constructs with an expression pattern similar to a GENSET gene expression pattern.

Detection of GENSET polypeptide expression and/or biological activity

- 5 The invention further relates to methods of detection of GENSET polypeptide expression and/or biological activity in a biological sample using the polynucleotide and polypeptide sequences described herein. Such method scan be used, for example, as a screen for normal or abnormal GENSET polypeptide expression and/or biological activity and, thus, can be used diagnostically. The biological sample for use in the methods of the present invention includes a suitable sample
- 10 from, for example, a mammal, particularly a human.

Detection of GENSET polypeptides

- The invention further relates to methods of detection of GENSET polypeptide or encoding polynucleotides in a sample using the sequences described herein and any techniques known to those skilled in the art. For example, a labeled polynucleotide probe having all or a functional
- 15 portion of the nucleotide sequence of a GENSET polypeptide-encoding polynucleotide can be used in a method to detect a GENSET polypeptide-encoding polynucleotide in a sample. In one embodiment, the sample is treated to render the polynucleotides in the sample available for hybridization to a polynucleotide probe, which can be DNA or RNA. The resulting treated sample is combined with a labeled polynucleotide probe having all or a portion of the nucleotide sequence
- 20 of the GENSET polypeptide-encoding cDNA or genomic sequence, under conditions appropriate for hybridization of complementary sequences to occur. Detection of hybridization of polynucleotides from the sample with the labeled nucleic probe indicates the presence of GENSET polypeptide-encoding polynucleotides in a sample. The presence of GENSET polypeptide-encoding mRNA is indicative of GENSET polypeptide-encoding gene expression.

- 25 Consequently, the invention comprises methods for detecting the presence of a polynucleotide comprising a nucleotide sequence selected from a group consisting of the polynucleotide sequences of the Sequence Listing, those of human cDNA clone inserts of the deposited clone pool, sequences fully complementary thereto, fragments and variants thereof in a sample. In a first embodiment, said method comprises the following steps of:
- 30 a) bringing into contact said sample and a nucleic acid probe or a plurality of nucleic acid probes which hybridize to said selected nucleotide sequence; and
- b) detecting the hybrid complex formed between said probe or said plurality of probes and said polynucleotide.

- In a preferred embodiment of the above detection method, said nucleic acid probe or said
- 35 plurality of nucleic acid probes is labeled with a detectable molecule. In another preferred embodiment of the above detection method, said nucleic acid probe or said plurality of nucleic acid probes has been immobilized on a substrate. In still another preferred embodiment, said nucleic

acid probe or said plurality of nucleic acid probes has a sequence comprised in a sequence complementary to said selected sequence.

In a second embodiment, said method comprises the steps of:

- 5 a) contacting said sample with amplification reaction reagents comprising a pair of amplification primers located on either side of the region of said nucleotide sequence to be amplified;
- b) performing an amplification reaction to synthesize amplification products containing said region of said selected nucleotide sequence; and
- c) detecting said amplification products.

- 10 In a preferred embodiment of the above detection method, when the polynucleotide to be amplified is a RNA molecule, preliminary reverse transcription and synthesis of a second cDNA strand are necessary to provide a DNA template to be amplified. In another preferred embodiment of the above detection method, the amplification product is detected by hybridization with a labeled probe having a sequence which is complementary to the amplified region. In still another
- 15 preferred embodiment, at least one of said amplification primer has a sequence comprised in said selected sequence or in the sequence complementary to said selected sequence.

- Alternatively, a method of detecting GENSET polypeptide expression in a test sample can be accomplished using any product which binds to a GENSET olypeptide of the present invention or a portion of a GENSET polypeptide. Such products may be antibodies, binding fragments of
- 20 antibodies, polypeptides able to bind specifically to GENSET polypeptides or fragments thereof, including GENSET polypeptide agonists and antagonists. Detection of specific binding to the antibody indicates the presence of a GENSET polypeptide in the sample (e.g., ELISA).

- Consequently, the invention is also directed to a method for detecting specifically the presence of a GENSET polypeptide according to the invention in a biological sample, said method
- 25 comprising the steps of:

- a) bringing into contact said biological sample with a product able to bind to a polypeptide of the invention or fragments thereof;
- b) allowing said product to bind to said polypeptide to form a complex; and
- c) detecting said complex.

- 30 In a preferred embodiment of the above detection method, the product is an antibody. In a more preferred embodiment, said antibody is labeled with a detectable molecule. In another more preferred embodiment of the above detection method, said antibody has been immobilized on a substrate.

- In addition, the invention also relates to methods of determining whether a GENSET gene product
- 35 (e.g. a polynucleotide or polypeptide) is present or absent in a biological sample, said methods comprising the steps of:

- a) obtaining said biological sample from a human or non-human animal,

- preferably a mammal;
- b) contacting said biological sample with a product able to bind to a GENSET polypeptide or encoding polynucleotide of the invention; and
- c) determining the presence or absence of said GENSET polypeptide-encoding gene product in said biological sample.

The present invention also relates to kits that can be used in the detection of GENSET polypeptide-encoding gene expression products. The kit can comprise a compound that specifically binds a GENSET polypeptide (e.g. binding proteins, antibodies or binding fragments thereof (e.g. F(ab')<sub>2</sub> fragments) or a GENSET polypeptide-encoding mRNA (e.g. a complementary probe or primer), for example, disposed within a container means. The kit can further comprise ancillary reagents, including buffers and the like.

Detection of GENSET polypeptide biological activity

The invention further includes methods of detecting specifically a GENSET polypeptide biological activity, and to identify compounds capable of modulating the activity of a GENSET polypeptide. Assessing the GENSET polypeptide biological activity may be performed by the detection of a change in any cellular property associated with the GENSET polypeptide, using a variety of techniques, including those described herein. To identify modulators of the polypeptides, a control is preferably used. For example, a control sample includes all of the same reagents but lacks the compound or agent being assessed; it is treated in the same manner as the test sample.

The present invention also relates to kits that can be used in the detection of GENSET polypeptide biological activity. The kit can comprise, e.g. substrates for GENSET polypeptides, GENSET-binding compounds, antibodies to GENSET polypeptides, etc., for example, disposed within a container means. The kit can further comprise ancillary reagents, including buffers and the like.

Identification of a specific context of GENSET polypeptide-encoding gene expression

When the expression pattern of a GENSET polypeptide-encoding mRNA shows that a GENSET polypeptide-encoding gene is specifically expressed in a given context, probes and primers specific for this gene as well as antibodies binding to the GENSET polypeptide-encoding polynucleotide may then be used as markers for the specific context. Examples of specific contexts are: specific expression in a given tissue/cell or tissue/cell type, expression at a given stage of development of a process such as embryo development or disease development, or specific expression in a given organelle. Such primers, probes, and antibodies are useful commercially to identify tissues/cells/organelles of unknown origin, for example, forensic samples, differentiated tumor tissue that has metastasized to foreign bodily sites, or to differentiate different tissue types in a tissue cross-section using any technique known to those skilled in the art including *in situ* PCR or

immunochemistry for example.

- For example, the cDNAs and proteins of the sequence listing and fragments thereof, may be used to distinguish human tissues/cells from non-human tissues/cells and to distinguish between human tissues/cells/organelles that do and do not express the polynucleotides comprising the
- 5 cDNAs. By knowing the expression pattern of a given GENSET polypeptide, either through routine experimentation or by using the instant disclosure, the polynucleotides and polypeptides of the present invention may be used in methods of determining the identity of an unknown tissue/cell sample/organelle. As part of determining the identity of an unknown tissue/cell sample/organelle, the polynucleotides and polypeptides of the present invention may be used to determine what the
- 10 unknown tissue/cell sample is and what the unknown sample is not. For example, if a cDNA is expressed in a particular tissue/cell type/organelle, and the unknown tissue/cell sample/organelle does not express the cDNA, it may be inferred that the unknown tissue/cells are either not human or not the same human tissue/cell type/organelle as that which expresses the cDNA. Determination of tissue/cell/organelle identity is based on methods that detect the presence or absence of the
- 15 mRNA (or corresponding cDNA) in a tissue/cell sample using methods well known in the art (e.g., hybridization, PCR based methods, immunoassays, immunochemistry, ELISA). Examples of such techniques are described in more detail below. Therefore, the invention encompasses uses of the polynucleotides and polypeptides of the invention as tissue markers. Consequently, the present invention encompasses methods of identification of a tissue/cell type/subcellular compartment,
- 20 wherein said method includes the steps of:
- a) contacting a biological sample which identity is to be assayed with a product able to bind a GENSET gene product; and
  - b) determining whether a GENSET gene product is expressed in said biological sample.

- 25 Products that are able to bind specifically to a GENSET gene product, namely a GENSET polypeptide or a GENSET polypeptide-encoding mRNA, include GENSET polypeptide binding proteins, antibodies or binding fragments thereof (e.g. F(ab')<sub>2</sub> fragments), as well as GENSET polynucleotide complementary probes and primers.

- Step b) may be performed using any detection method known to those skilled in the art
- 30 including those disclosed herein, especially in the section entitled "Detection of GENSET polypeptide expression and/or biological activity".

Identification of Tissue Types or Cell Species by Means of Labeled Tissue Specific Antibodies

- Identification of specific tissues is accomplished by the visualization of tissue specific
- 35 antigens by means of antibody preparations which are conjugated, directly (e.g., green fluorescent protein) or indirectly to a detectable marker. Selected labeled antibody species bind to their specific antigen binding partner in tissue sections, cell suspensions, or in extracts of soluble

proteins from a tissue sample to provide a pattern for qualitative or semi-qualitative interpretation.

#### A. Immunohistochemical Techniques

Purified, high-titer antibodies, prepared as described above, are conjugated to a detectable  
5 marker, as described, for example, by Fudenberg, (1980) Chap. 26 in: Basic 503 Clinical  
Immunology, 3rd Ed. Lange, Los Altos, California or Rose *et al.*, (1980) Chap. 12 in: Methods in  
Immunodiagnosis, 2d Ed. John Wiley 503 Sons, New York, which disclosures are hereby  
incorporated by reference in their entireties.

A fluorescent marker, either fluorescein or rhodamine, is preferred, but antibodies can also  
10 be labeled with an enzyme that supports a color producing reaction with a substrate, such as  
horseradish peroxidase. Markers can be added to tissue-bound antibody in a second step, as  
described below. Alternatively, the specific anti-tissue antibodies can be labeled with ferritin or  
other electron dense particles, and localization of the ferritin coupled antigen-antibody complexes  
achieved by means of an electron microscope. In yet another approach, the antibodies are  
15 radiolabeled, with, for example  $^{125}\text{I}$ , and detected by overlaying the antibody treated preparation  
with photographic emulsion. Preparations to carry out the procedures can comprise monoclonal or  
polyclonal antibodies to a single protein or peptide identified as specific to a tissue type, for  
example, brain tissue, or antibody preparations to several antigenically distinct tissue specific  
antigens can be used in panels, independently or in mixtures, as required. Tissue sections and cell  
20 suspensions are prepared for immunohistochemical examination according to common histological  
techniques. Multiple cryostat sections (about 4  $\mu\text{m}$ , unfixed) of the unknown tissue and known  
control, are mounted and each slide covered with different dilutions of the antibody preparation.  
Sections of known and unknown tissues should also be treated with preparations to provide a  
positive control, a negative control, for example, pre-immune sera, and a control for non-specific  
25 staining, for example, buffer. Treated sections are incubated in a humid chamber for 30 min at  
room temperature, rinsed, then washed in buffer for 30-45 min. Excess fluid is blotted away, and  
the marker developed. If the tissue specific antibody was not labeled in the first incubation, it can  
be labeled at this time in a second antibody-antibody reaction, for example, by adding fluorescein-  
or enzyme-conjugated antibody against the immunoglobulin class of the antiserum-producing  
30 species, for example, fluorescein labeled antibody to mouse IgG. Such labeled sera are  
commercially available. The antigen found in the tissues by the above procedure can be quantified  
by measuring the intensity of color or fluorescence on the tissue section, and calibrating that signal  
using appropriate standards.

#### 35 B. Identification of Tissue Specific Soluble Proteins

The visualization of tissue specific proteins and identification of unknown tissues from that  
procedure is carried out using the labeled antibody reagents and detection strategy as described for

immunohistochemistry; however the sample is prepared according to an electrophoretic technique to distribute the proteins extracted from the tissue in an orderly array on the basis of molecular weight for detection. For example, Western Blot Analysis, see, e.g., Davis *et al.*, Basic Methods in Molecular Biology, ed., Elsevier Press, NY (1986), Section 19-3.

- 5 In either procedure A or B, a detectable label can be attached to the primary tissue antigen-  
primary antibody complex according to various strategies and permutations thereof. In a  
straightforward approach, the primary specific antibody can be labeled; alternatively, the unlabeled  
complex can be bound by a labeled secondary anti-IgG antibody. In other approaches, either the  
primary or secondary antibody is conjugated to a biotin molecule, which can, in a subsequent step,  
10 bind an avidin conjugated marker. According to yet another strategy, enzyme labeled or  
radioactive protein A, which has the property of binding to any IgG, is bound in a final step to  
either the primary or secondary antibody. The visualization of tissue specific antigen binding at  
levels above those seen in control tissues to one or more tissue specific antibodies, prepared from  
the gene sequences identified from cDNA sequences, can identify tissues of unknown origin, for  
15 example, forensic samples, or differentiated tumor tissue that has metastasized to foreign bodily  
sites.

#### Screening and diagnosis of abnormal GENSET polypeptide expression and/or biological activity

- Moreover, antibodies and/or primers specific for GENSET polypeptide expression may  
20 also be used to identify abnormal GENSET polypeptide expression and/or biological activity, and  
subsequently to screen and/or diagnose disorders associated with abnormal GENSET polypeptide  
expression. For example, a particular disease may result from lack of expression, over expression,  
or under expression of a GENSET polypeptide-encoding mRNA. By comparing mRNA  
expression patterns and quantities in samples taken from healthy individuals with those from  
25 individuals suffering from a particular disorder, genes responsible for this disorder may be  
identified. Primers, probes and antibodies specific for this GENSET polypeptide may then be used  
to elaborate kits of screening and diagnosis for a disorder in which the gene of interest is  
specifically expressed or in which its expression is specifically dysregulated, i.e. underexpressed or  
overexpressed.

30

#### Screening for specific disorders

- The present invention also relates to methods and uses of GENSET polypeptides for  
identifying individuals having elevated or reduced levels of GENSET polypeptides, which  
individuals are likely to benefit from therapies to suppress or enhance GENSET polypeptide-  
35 encoding gene expression, respectively. One example of such methods and uses comprises the  
steps of:

- a) obtaining from a mammal a biological sample;

- b) detecting the presence in said sample of a GENSET polypeptide-encoding gene product (mRNA or protein);
- c) comparing the amount of said GENSET polypeptide-encoding gene product present in said sample with that of a control sample; and
- 5 d) determining whether said human or non-human mammal has a reduced or elevated level of GENSET gene expression compared to the control sample.

A biological sample from a subject affected by, or at risk of developing, any disease or condition associated with a GENSET polypeptide can be screened for the presence of increased or decreased levels of GENSET gene product, relative to a normal population (standard or control),  
10 with an increased or decreased level of the GENSET polypeptide relative to the normal population being indicative of predisposition to or a present indication of the disease or condition, or any symptom associated with the disease or condition. Such individuals would be candidates for therapies, e.g., treatment with pharmaceutical compositions comprising the GENSET polypeptide, a polynucleotide encoding the GENSET polypeptide, or any other compound that affects the  
15 expression or activity of the GENSET polypeptide. Generally, the identification of elevated levels of the GENSET polypeptide in a patient would be indicative of an individual that would benefit from treatment with agents that suppress GENSET polypeptide expression or activity, and the identification of low levels of the GENSET polypeptide in a patient would be indicative of an individual that would benefit from agents that induce GENSET expression or activity.

20 Biological samples suitable for use in this method include any biological fluids, including, but not limited to, blood, saliva, milk, and urine. Tissue samples (e.g. biopsies) can also be used in the method of the invention, including samples derived from any tissue associated with GENSET gene expression as determined by any method common to the art such as those described herein.. Cell cultures or cell extracts derived, for example, from tissue biopsies can also be used. The  
25 detection step of the present method can be performed using standard protocols for protein/mRNA detection. Examples of suitable protocols include Northern blot analysis, immunoassays (e.g. RIA, Western blots, immunohistochemical analyses), and PCR.

Thus, the present invention further relates to methods and uses of GENSET polypeptides for identifying individuals or non-human animals at increased risk for developing, or present state  
30 of having, certain diseases/disorders associated with abnormal GENSET polypeptide expression or biological activity. One example of such methods comprises the steps of:

- a) obtaining from a human or non-human mammal a biological sample;
- b) detecting the presence in said sample of a GENSET gene product (mRNA or protein);
- 35 c) comparing the amount of said GENSET gene product present in said sample with that of a control sample; and
- d) determining whether said human or non-human mammal is at increased risk

for developing, or present state of having, a diseases or disorder.

- In preferred embodiments, the biological sample is taken from animals presenting any symptom associated with any disease or condition associated with a GENSET gene product. In accordance with this method, the presence in the sample of altered (e.g. increased or decreased) levels of the GENSET product indicates that the subject is predisposed to the disease or condition. Biological samples suitable for use in this method include biological fluids including, but not limited to, blood, saliva, milk, and urine. Tissue samples (e.g. biopsies) can also be used in the method of the invention. Cell cultures or cell extracts derived, for example, from tissue biopsies can also be used.
- 10 The diagnostic methodologies described herein are applicable to both humans and non-human mammals.

#### Detection of GENSET gene mutations

- The invention also encompasses methods and uses of GENSET polynucleotides to detect mutations in GENSET polynucleotides of the invention. Such methods may advantageously be used to detect mutations occurring in GENSET genes and preferably in their regulatory regions. When the mutation was proven to be associated with a disease, the detection of such mutations may be used for screening and diagnosis purposes.

- In one embodiment of the oligonucleotide arrays of the invention, an oligonucleotide probe matrix may advantageously be used to detect mutations occurring in GENSET genes and preferably in their regulatory regions. For this particular purpose, probes are specifically designed to have a nucleotide sequence allowing their hybridization to the genes that carry known mutations (either by deletion, insertion or substitution of one or several nucleotides). By known mutations, it is meant, mutations on the GENSET genes that have been identified according, for example to the technique used by Huang *et al.*, (1996) Cancer Res 56(5):1137-1141 or Samson *et al.*, (1996) Nature, 382(6593):722-725, which disclosures are hereby incorporated by reference in their entireties.

- Another technique that is used to detect mutations in GENSET genes is the use of a high-density DNA array. Each oligonucleotide probe constituting a unit element of the high density DNA array is designed to match a specific subsequence of a GENSET genomic DNA or cDNA. Thus, an array consisting of oligonucleotides complementary to subsequences of the target gene sequence is used to determine the identity of the target sequence with the wild gene sequence, measure its amount, and detect differences between the target sequence and the reference wild gene sequence of the GENSET gene. In one such design, termed 4L tiled array, is implemented a set of four probes (A, C, G, T), preferably 15-nucleotide oligomers. In each set of four probes, the perfect complement will hybridize more strongly than mismatched probes. Consequently, a nucleic acid target of length L is scanned for mutations with a tiled array containing 4L probes, the

whole probe set containing all the possible mutations in the known wild reference sequence. The hybridization signals of the 15-mer probe set tiled array are perturbed by a single base change in the target sequence. As a consequence, there is a characteristic loss of signal or a "footprint" for the probes flanking a mutation position. This technique was described by Chee *et al.*, (1996)

5 Science. 274:610-614, which disclosure is hereby incorporated by reference in its entirety.

#### Construction of DNA constructs with a GENSET gene expression pattern

In addition, characterization of the spatial and temporal expression patterns and expression levels of GENSET polypeptide-encoding mRNAs is also useful for constructing expression vectors  
10 capable of producing a desired level of gene product in a desired spatial or temporal manner, as discussed below.

#### DNA Constructs That Direct Temporal And Spatial GENSET Gene Expression In Recombinant Cell Hosts And In Transgenic Animals.

15 In order to study the physiological and phenotypic consequences of a lack of synthesis of a GENSET polypeptide, both at the cellular level and at the multi cellular organism level, the invention also encompasses DNA constructs and recombinant vectors enabling a conditional expression of a specific allele of a GENSET polypeptide-encoding genomic sequence or cDNA and also of a copy of this genomic sequence or cDNA harboring substitutions, deletions, or  
20 additions of one or more bases as regards to a polynucleotide of the present regulatory sequence, but preferably in the 5'-regulatory sequence or in an exon of the GENSET polypeptide-encoding genomic sequence or within the GENSET polypeptide-encoding cDNA.

A first preferred DNA construct is based on the tetracycline resistance operon *tet* from *E. coli* transposon Tn10 for controlling the GENSET gene expression, such as described by Gossen *et al.*, (1992) Proc. Natl. Acad. Sci. USA. 89:5547-5551; Gossen *et al.*, (1995) Science 268:1766-  
25 1769; and Furth P.A. *et al.* (1994) Proc. Natl. Acad. Sci USA. 91:9302-9306, which disclosures are hereby incorporated by reference in their entirety. Such a DNA construct contains seven *tet* operator sequences from Tn10 (*tetop*) that are fused to either a minimal promoter or a 5'-regulatory sequence of the GENSET gene, said minimal promoter or said GENSET polynucleotide regulatory  
30 sequence being operably linked to a polynucleotide of interest that codes either for a sense or an antisense oligonucleotide or for a polypeptide, including a GENSET polypeptide, or a peptide fragment thereof. This DNA construct is functional as a conditional expression system for the nucleotide sequence of interest when the same cell also comprises a nucleotide sequence coding for either the wild type (tTA) or the mutant (rTA) repressor fused to the activating domain of viral  
35 protein VP16 of herpes simplex virus, placed under the control of a promoter, such as the HCMVIE1 enhancer/promoter or the MMTV-LTR. Indeed, a preferred DNA construct of the invention comprise both the polynucleotide containing the *tet* operator sequences and the

polynucleotide containing a sequence coding for the tTA or the rTA repressor. In a specific embodiment, the conditional expression DNA construct contains the sequence encoding the mutant tetracycline repressor rTA, the expression of the polynucleotide of interest is silent in the absence of tetracycline and induced in its presence.

5

DNA Constructs Allowing Homologous Recombination: Replacement Vectors

A second preferred DNA construct will comprise, from 5'-end to 3'-end: (a) a first nucleotide sequence that is found in the GENSET polypeptide-encoding genomic sequence; (b) a nucleotide sequence comprising a positive selection marker, such as the marker for neomycin resistance (*neo*); and (c) a second nucleotide sequence that is found in the GENSET polypeptide-encoding genomic sequence, and is located on the genome downstream the first GENSET polypeptide-encoding nucleotide sequence (a).

In a preferred embodiment, this DNA construct also comprises a negative selection marker located upstream of the nucleotide sequence (a) or downstream from the nucleotide sequence (c). Preferably, the negative selection marker comprises the thymidine kinase (*tk*) gene [Thomas *et al.* (1986), Cell. 44:419-428], the hygromycin beta gene [Te Riele *et al.* (1990), Nature. 348:649-651], the *hprt* gene [Van der Lugt *et al.* (1991), Gene. 105:263-267; Reid *et al.*, (1990) Proc. Natl. Acad. Sci. U.S.A. 87:4299-4303] or the Diphtheria toxin A fragment (*Dt-A*) gene [Nada *et al.*, (1993) Cell 73:1125-1135; Yagi, T., *et al.* (1990), Proc. Natl. Acad. Sci. U.S.A. 87:9918-992], which disclosures are hereby incorporated by reference in their entireties. Preferably, the positive selection marker is located within a GENSET exon sequence so as to interrupt the sequence encoding a GENSET polypeptide. These replacement vectors are described, for example, by Thomas *et al.* (1986; 1987), Mansour *et al.* (1988) and Koller *et al.*, (1992) Annu. Rev. Immunol. 10:705-730.

The first and second nucleotide sequences (a) and (c) may be indifferently located within a GENSET polypeptide-encoding regulatory sequence, an intronic sequence, an exon sequence or a sequence containing both regulatory and/or intronic and/or exon sequences. The size of the nucleotide sequences (a) and (c) ranges from 1 to 50 kb, preferably from 1 to 10 kb, more preferably from 2 to 6 kb and most preferably from 2 to 4 kb.

30

DNA Constructs Allowing Homologous Recombination: Cre-LoxP System.

These new DNA constructs make use of the site specific recombination system of the P1 phage. The P1 phage possesses a recombinase called Cre which interacts specifically with a 34 base pairs *loxP* site. The *loxP* site is composed of two palindromic sequences of 13 bp separated by a 8 bp conserved sequence [Hoess *et al.*, (1986) Nucleic Acids Res. 14:2287-2300], which disclosure is hereby incorporated by reference in its entirety. The recombination by the Cre enzyme between two *loxP* sites having an identical orientation leads to the deletion of the DNA

fragment.

The Cre-loxP system used in combination with a homologous recombination technique has been first described by Gu H. *et al.*, (1993) Cell 73:1155-1164 and Gu H. *et al.*, (1994) Science 265:103-106, which disclosures are hereby incorporated by reference in their entireties. Briefly, a nucleotide sequence of interest to be inserted in a targeted location of the genome harbors at least two loxP sites in the same orientation and located at the respective ends of a nucleotide sequence to be excised from the recombinant genome. The excision event requires the presence of the recombinase (Cre) enzyme within the nucleus of the recombinant cell host. The recombinase enzyme may be brought at the desired time either by (a) incubating the recombinant cell hosts in a culture medium containing this enzyme, by injecting the Cre enzyme directly into the desired cell, such as described by Araki *et al.*, (1995) Proc. Natl. Acad. Sci. U S A. 92(1):160-4, which disclosure is hereby incorporated by reference in its entirety, or by lipofection of the enzyme into the cells, such as described by Baubonis *et al* (1993) *Nucleic Acids Res.* 21(9):2025-9), which disclosure is hereby incorporated by reference in its entirety; (b) transfecting the cell host with a vector comprising the Cre coding sequence operably linked to a promoter functional in the recombinant cell host, which promoter being optionally inducible, said vector being introduced in the recombinant cell host, such as described by Gu *et al.* (1993) and Sauer *et al.*, (1988) Proc. Natl. Acad. Sci. U.S.A. 85:5166-5170, which disclosures are hereby incorporated by reference in their entireties; (c) introducing in the genome of the cell host a polynucleotide comprising the Cre coding sequence operably linked to a promoter functional in the recombinant cell host, which promoter is optionally inducible, and said polynucleotide being inserted in the genome of the cell host either by a random insertion event or an homologous recombination event, such as described by Gu *et al.* (1994).

In a specific embodiment, the vector containing the sequence to be inserted in the GENSET gene by homologous recombination is constructed in such a way that selectable markers are flanked by loxP sites of the same orientation, it is possible, by treatment by the Cre enzyme, to eliminate the selectable markers while leaving the GENSET sequences of interest that have been inserted by an homologous recombination event. Again, two selectable markers are needed: a positive selection marker to select for the recombination event and a negative selection marker to select for the homologous recombination event. Vectors and methods using the Cre-loxP system are described by Zou, *et al.*, (1994) Curr. Biol. 4:1099-1103, which disclosure is hereby incorporated by reference in its entirety.

Thus, a third preferred DNA construct of the invention comprises, from 5'-end to 3'-end: (a) a first nucleotide sequence that is comprised in the GENSET genomic sequence; (b) a nucleotide sequence comprising a polynucleotide encoding a positive selection marker, said nucleotide sequence comprising additionally two sequences defining a site recognized by a recombinase, such as a loxP site, the two sites being placed in the same orientation; and (c) a

second nucleotide sequence that is comprised in the GENSET genomic sequence, and is located on the genome downstream of the first GENSET nucleotide sequence (a).

The sequences defining a site recognized by a recombinase, such as a *loxP* site, are preferably located within the nucleotide sequence (b) at suitable locations bordering the nucleotide sequence for which the conditional excision is sought. In one specific embodiment, two *loxP* sites are located at each side of the positive selection marker sequence, in order to allow its excision at a desired time after the occurrence of the homologous recombination event.

In a preferred embodiment of a method using the third DNA construct described above, the excision of the polynucleotide fragment bordered by the two sites recognized by a recombinase, preferably two *loxP* sites, is performed at a desired time, due to the presence within the genome of the recombinant host cell of a sequence encoding the Cre enzyme operably linked to a promoter sequence, preferably an inducible promoter, more preferably a tissue-specific promoter sequence and most preferably a promoter sequence which is both inducible and tissue-specific, such as described by Gu *et al.* (1994).

The presence of the Cre enzyme within the genome of the recombinant cell host may result from the breeding of two transgenic animals, the first transgenic animal bearing the GENSET-derived sequence of interest containing the *loxP* sites as described above and the second transgenic animal bearing the *Cre* coding sequence operably linked to a suitable promoter sequence, such as described by Gu *et al.* (1994).

Spatio-temporal control of the Cre enzyme expression may also be achieved with an adenovirus based vector that contains the Cre gene thus allowing infection of cells, or *in vivo* infection of organs, for delivery of the Cre enzyme, such as described by Anton and Graham, (1995), J. Virol., 69: 4600-4606 and Kanegae *et al.*, (1995) Nucl. Acids Res. 23:3816-3821, which disclosures are hereby incorporated by reference in their entireties.

The DNA constructs described above may be used to introduce a desired nucleotide sequence of the invention, preferably a GENSET genomic sequence or a GENSET cDNA sequence, and most preferably an altered copy of a GENSET genomic or cDNA sequence, within a predetermined location of the targeted genome, leading either to the generation of an altered copy of a targeted gene (knock-out homologous recombination) or to the replacement of a copy of the targeted gene by another copy sufficiently homologous to allow an homologous recombination event to occur (knock-in homologous recombination).

#### **MODIFYING GENSET POLYOPTIDE EXPRESSION AND/OR BIOLOGICAL ACTIVITY**

Modifying endogenous GENSET expression and/or biological activity is expressly contemplated by the present invention.

#### **Screening for compounds that modulate GENSET expression and/or biological activity**

The present invention further relates to compounds able to modulate GENSET expression

and/or biological activity and methods to use these compounds. Such compounds may interact with the regulatory sequences of GENSET genes or they may interact with GENSET polypeptides directly or indirectly.

#### Compounds Interacting With GENSET Regulatory Sequences

5           The present invention also concerns a method for screening substances or molecules that are able to interact with the regulatory sequences of a GENSET gene, such as for example promoter or enhancer sequences in untranscribed regions of the genomic DNA, as determined using any techniques known to those skilled in the art including those described in the section entitled "Identification of Promoters in Cloned Upstream Sequences, or such as regulatory  
10 sequences located in untranslated regions of GENSET mRNA.

Sequences within untranscribed or untranslated regions of polynucleotides of the invention may be identified by comparison to databases containing known regulatory sequence such as transcription start sites, transcription factor binding sites, promoter sequences, enhancer sequences, 5'UTR and 3'UTR elements [Pesole *et al.*, (2000) Nucleic Acids Res, 28(1):193-196; <http://igs-server.cnrs-mrs.fr/~gauthere/UTR/index.html>]. Alternatively, the regulatory sequences of interest  
15 may be identified through conventional mutagenesis or deletion analyses of reporter plasmids using, for instance, techniques described in the section entitled "Identification of Promoters in Cloned Upstream Sequences".

Following the identification of potential GENSET regulatory sequences, proteins which  
20 interact with these regulatory sequences may be identified as described below.

Gel retardation assays may be performed independently in order to screen candidate molecules that are able to interact with the regulatory sequences of the GENSET gene, such as described by Fried and Crothers, (1981) Nucleic Acids Res. 9:6505-6525, Garner and Revzin, (1981) Nucleic Acids Res 9:3047-3060 and Dent and Latchman (1993) The DNA mobility shift  
25 assay. In: Transcription Factors: A Practical Approach (Latchman DS, ed.) pp1-26. Oxford: IRL Press, the teachings of these publications being herein incorporated by reference. These techniques are based on the principle according to which a DNA or mRNA fragment which is bound to a protein migrates slower than the same unbound DNA or mRNA fragment. Briefly, the target nucleotide sequence is labeled. Then the labeled target nucleotide sequence is brought into contact  
30 with either a total nuclear extract from cells containing regulation factors, or with different candidate molecules to be tested. The interaction between the target regulatory sequence of the GENSET gene and the candidate molecule or the regulation factor is detected after gel or capillary electrophoresis through a retardation in the migration.

Nucleic acids encoding proteins which are able to interact with the promoter sequence of  
35 the GENSET gene, more particularly the polynucleotides of the 5' and 3' regulatory region or a fragment or variant thereof, may be identified by using a one-hybrid system, such as that described in the booklet enclosed in the Matchmaker One-Hybrid System kit from Clontech (Catalog Ref.

no. K1603-1, the technical teachings of which are herein incorporated by reference).

#### Ligands interacting with GENSET polypeptides

For the purpose of the present invention, a ligand means a molecule, such as a protein, a peptide, an antibody or any synthetic chemical compound capable of binding to a GENSET protein or one of its fragments or variants or to modulate the expression of the polynucleotide coding for GENSET or a fragment or variant thereof.

In the ligand screening method according to the present invention, a biological sample or a defined molecule to be tested as a putative ligand of a GENSET protein is brought into contact with the corresponding purified GENSET protein, for example the corresponding purified recombinant GENSET protein produced by a recombinant cell host as described herein, in order to form a complex between this protein and the putative ligand molecule to be tested.

As an illustrative example, to study the interaction of a polypeptide of the invention, with drugs or small molecules, such as molecules generated through combinatorial chemistry approaches, the microdialysis coupled to HPLC method described by Wang, *et al.* (1997), *Chromatographia*, 44 : 205-208 or the affinity capillary electrophoresis method described by Bush *et al.*, (1997), *J. Chromatogr.*, 777 : 311-328, the disclosures of which are incorporated by reference, can be used.

In further methods, peptides, drugs, fatty acids, lipoproteins, or small molecules which interact with a may be identified using assays known in the art. For example, the molecule to be tested for binding is labeled with a detectable label, such as a fluorescent, radioactive, or enzymatic tag and placed in contact with immobilized GENSET protein, or a fragment thereof under conditions which permit specific binding to occur. After removal of non-specifically bound molecules, bound molecules are detected using appropriate means.

Various candidate substances or molecules can be assayed for interaction with a GENSET polypeptide. These substances or molecules include, without being limited to, natural or synthetic organic compounds or molecules of biological origin such as polypeptides. When the candidate substance or molecule comprises a polypeptide, this polypeptide may be the resulting expression product of a phage clone belonging to a phage-based random peptide library, or alternatively the polypeptide may be the resulting expression product of a cDNA library cloned in a vector suitable for performing a two-hybrid screening assay.

#### A. Candidate ligands obtained from random peptide libraries

In a particular embodiment of the screening method, the putative ligand is the expression product of a DNA insert contained in a phage vector [Parmley and Smith, (1988) *Gene* 73:305-318]. Specifically, random peptide phages libraries are used. The random DNA inserts encode for peptides of 8 to 20 amino acids in length [Oldenburg *et al.*, (1992), *Proc. Natl. Acad. Sci. USA*

89:5393-5397; Valadon *et al.*, (1996), J. Mol. Biol., 261:11-22; Lucas (1994), In: Development and Clinical Uses of Haemophilus b Conjugate; Westerink (1995), Proc. Natl. Acad. Sci USA., 92:4021-4025; Felici, (1991), J. Mol. Biol., 222:301-310], which disclosures are hereby incorporated by reference in their entireties. According to this particular embodiment, the

5 recombinant phages expressing a protein that binds to an immobilized GENSET protein is retained and the complex formed between the GENSET protein and the recombinant phage may be subsequently immunoprecipitated by a polyclonal or a monoclonal antibody directed against the GENSET protein.

Once the ligand library in recombinant phages has been constructed, the phage population  
10 is brought into contact with the immobilized GENSET protein. Then the preparation of complexes is washed in order to remove the non-specifically bound recombinant phages. The phages that bind specifically to the GENSET protein are then eluted by a buffer (acid pH) or immunoprecipitated by the monoclonal antibody produced by the hybridoma anti-GENSET, and this phage population is subsequently amplified by an over-infection of bacteria (for example E.  
15 coli). The selection step may be repeated several times, preferably 2-4 times, in order to select the more specific recombinant phage clones. The last step comprises characterizing the peptide produced by the selected recombinant phage clones either by expression in infected bacteria and isolation, expressing the phage insert in another host-vector system, or sequencing the insert contained in the selected recombinant phages.

20

B. Candidate ligands obtained by competition experiments.

Alternatively, peptides, drugs or small molecules which bind to polypeptide of the present invention may be identified in competition experiments. In such assays, the GENSET protein, or a fragment thereof, is immobilized to a surface, such as a plastic plate. Increasing amounts of the  
25 peptides, drugs or small molecules are placed in contact with the immobilized GENSET protein, or a fragment thereof, in the presence of a detectable labeled known GENSET protein ligand. For example, the GENSET ligand may be detectably labeled with a fluorescent, radioactive, or enzymatic tag. The ability of the test molecule to bind the GENSET protein, or a fragment thereof, is determined by measuring the amount of detectably labeled known ligand bound in the presence  
30 of the test molecule. A decrease in the amount of known ligand bound to the GENSET protein, or a fragment thereof, when the test molecule is present indicated that the test molecule is able to bind to the GENSET protein, or a fragment thereof.

C. Candidate ligands obtained by affinity chromatography.

35 Proteins or other molecules interacting with a polypeptide of the present invention, can also be found using affinity columns which contain the GENSET protein, or a fragment thereof. The GENSET protein, or a fragment thereof, may be attached to the column using conventional

techniques including chemical coupling to a suitable column matrix such as agarose, Affi Gel®, or other matrices familiar to those of skill in art. In some embodiments of this method, the affinity column contains chimeric proteins in which the GENSET protein, or a fragment thereof, is fused to glutathion S transferase (GST). A mixture of cellular proteins or pool of expressed proteins as described above is applied to the affinity column. Proteins or other molecules interacting with the GENSET protein, or a fragment thereof, attached to the column can then be isolated and analyzed on 2-D electrophoresis gel as described in Ramunsen *et al.*, (1997), Electrophoresis, 18 : 588-598, the disclosure of which is incorporated by reference. Alternatively, the proteins retained on the affinity column can be purified by electrophoresis based methods and sequenced. The same method can be used to isolate antibodies, to screen phage display products, or to screen phage display human antibodies.

D. Candidate ligands obtained by optical biosensor methods

Proteins interacting with a polypeptide of the present invention, can also be screened by using an Optical Biosensor as described in Edwards and Leatherbarrow, (1997) Analytical Biochemistry, 246, 1-6 and also in Szabo *et al.*, (1995) Curr Opin Struct Biol 5, 699-705, the disclosures of which are incorporated by reference. This technique permits the detection of interactions between molecules in real time, without the need of labeled molecules. This technique is based on the surface plasmon resonance (SPR) phenomenon. Briefly, the candidate ligand molecule to be tested is attached to a surface (such as a carboxymethyl dextran matrix). A light beam is directed towards the side of the surface that does not contain the sample to be tested and is reflected by said surface. The SPR phenomenon causes a decrease in the intensity of the reflected light with a specific association of angle and wavelength. The binding of candidate ligand molecules cause a change in the refraction index on the surface, which change is detected as a change in the SPR signal. For screening of candidate ligand molecules or substances that are able to interact with the GENSET protein, or a fragment thereof, the GENSET protein, or a fragment thereof, is immobilized onto a surface. This surface comprises one side of a cell through which flows the candidate molecule to be assayed. The binding of the candidate molecule on the GENSET protein, or a fragment thereof, is detected as a change of the SPR signal. The candidate molecules tested may be proteins, peptides, carbohydrates, lipids, or small molecules generated by combinatorial chemistry. This technique may also be performed by immobilizing eukaryotic or prokaryotic cells or lipid vesicles exhibiting an endogenous or a recombinantly expressed GENSET protein at their surface.

The main advantage of the method is that it allows the determination of the association rate between the GENSET protein and molecules interacting with the GENSET protein. It is thus possible to select specifically ligand molecules interacting with the GENSET protein, or a fragment thereof, through strong or conversely weak association constants.

E. Candidate ligands obtained through a two-hybrid screening assay.

The yeast two-hybrid system is designed to study protein-protein interactions *in vivo* (Fields and Song, 1989), which disclosure is hereby incorporated by reference in its entirety, and  
 5 relies upon the fusion of a bait protein to the DNA binding domain of the yeast Gal4 protein. This technique is also described in the US Patent No. US 5,667,973 and the US Patent No. 5,283,173, the technical teachings of both patents being herein incorporated by reference.

The general procedure of library screening by the two-hybrid assay may be performed as described by Harper *et al.*, (1993), Cell, 75 : 805-816 or as described by Cho *et al.*, (1998), Proc.  
 10 Natl. Acad. Sci. USA, 95(7):3752-3757 or also Fromont-Racine *et al.*, (1997), Nature Genetics, 16(3) : 277-282, which disclosures are hereby incorporated by reference in their entireties.

The bait protein or polypeptide comprises a polypeptide of the present invention.

More precisely, the nucleotide sequence encoding the GENSET polypeptide or a fragment or variant thereof is fused to a polynucleotide encoding the DNA binding domain of the GAL4  
 15 protein, the fused nucleotide sequence being inserted in a suitable expression vector, for example pAS2 or pM3.

Then, a human cDNA library is constructed in a specially designed vector, such that the human cDNA insert is fused to a nucleotide sequence in the vector that encodes the transcriptional domain of the GAL4 protein. Preferably, the vector used is the pACT vector. The polypeptides encoded  
 20 by the nucleotide inserts of the human cDNA library are termed "prey" polypeptides.

A third vector contains a detectable marker gene, such as beta galactosidase gene or CAT gene that is placed under the control of a regulation sequence that is responsive to the binding of a complete Gal4 protein containing both the transcriptional activation domain and the DNA binding domain. For example, the vector pG5EC may be used.

25 Two different yeast strains are also used. As an illustrative but non limiting example the two different yeast strains may be the followings :

- 190, the phenotype of which is (MATa, Leu2-3, 112 ura3-12, trp1-901, his3-D200, ade2-101, gal4Dgal180D URA3 GAL-LacZ, LYS GAL-HIS3, cyh<sup>r</sup>);
- 187, the phenotype of which is (MATa gal4 gal80 his3 trp1-901 ade2-101 ura3-52 leu2-3,  
 30 -112 URA3 GAL-lacZmet<sup>r</sup>), which is the opposite mating type of Y190.

Briefly, 20 µg of pAS2/GENSET and 20 µg of pACT-cDNA library are co-transformed into yeast strain Y190. The transformants are selected for growth on minimal media lacking histidine, leucine and tryptophan, but containing the histidine synthesis inhibitor 3-AT (50 mM). Positive colonies are screened for beta galactosidase by filter lift assay. The double positive  
 35 colonies (His<sup>+</sup>, beta-gal<sup>+</sup>) are then grown on plates lacking histidine, leucine, but containing tryptophan and cycloheximide (10 mg/ml) to select for loss of pAS2/GENSET plasmids but retention of pACT-cDNA library plasmids. The resulting Y190 strains are mated with Y187

strains expressing GENSET or non-related control proteins; such as cyclophilin B, lamin, or SNF1, as Gal4 fusions as described by Harper *et al.* (1993) and by Bram *et al.*, (1993), Mol. Cell Biol., 13:4760-4769, which disclosures are hereby incorporated by reference in their entireties, and screened for beta galactosidase by filter lift assay. Yeast clones that are beta gal- after mating with the control Gal4 fusions are considered false positives.

In another embodiment of the two-hybrid method according to the invention, interaction between the GENSET or a fragment or variant thereof with cellular proteins may be assessed using the Matchmaker Two Hybrid System 2 (Catalog No. K1604-1, Clontech). As described in the manual accompanying the kit, the disclosure of which is incorporated herein by reference, nucleic acids encoding the GENSET protein or a portion thereof, are inserted into an expression vector such that they are in frame with DNA encoding the DNA binding domain of the yeast transcriptional activator GAL4. A desired cDNA, preferably human cDNA, is inserted into a second expression vector such that they are in frame with DNA encoding the activation domain of GAL4. The two expression plasmids are transformed into yeast and the yeast are plated on selection medium which selects for expression of selectable markers on each of the expression vectors as well as GAL4 dependent expression of the HIS3 gene. Transformants capable of growing on medium lacking histidine are screened for GAL4 dependent lacZ expression. Those cells which are positive in both the histidine selection and the lacZ assay contain interaction between GENSET and the protein or peptide encoded by the initially selected cDNA insert.

#### Compounds Modulating GENSET biological activity

Another method of screening for compounds that modulate GENSET expression and/or biological activity is by measuring the effects of test compounds on specific biological activity, e.g. a GENSET biological activity in a host cell. In one embodiment, the present invention relates to a method of identifying an agent which alters GENSET biological activity, wherein a nucleic acid construct comprising a nucleic acid which encodes a mammalian GENSET polypeptide is introduced into a host cell. The host cells produced are maintained under conditions appropriate for expression of the encoded mammalian GENSET polypeptides, whereby the nucleic acid is expressed. The host cells are then contacted with a compound to be assessed (an "agent," or "test agent"), and the properties of the cells are assessed. Detection of a change in any GENSET polypeptide-associated property in the presence of the agent indicates that the agent alters GENSET activity. In a particular embodiment, the invention relates to a method of identifying an agent which is an activator of GENSET activity, wherein detection of an increase of any GENSET polypeptide-associated property in the presence of the agent indicates that the agent activates GENSET activity. In another particular embodiment, the invention relates to a method of identifying an agent which is an inhibitor of GENSET activity, wherein detection of a decrease of any GENSET polypeptide-associated property in the presence of the agent indicates that the agent

inhibits GENSET activity.

In a particular embodiment, a high throughput screen can be used to identify agents that activate (enhance) or inhibit GENSET activity (See e.g., PCT publication WO 98/45438, which disclosure is hereby incorporated by reference in its entirety). For example, the method of  
5 identifying an agent which alters GENSET activity can be performed as follows. A nucleic acid construct comprising a polynucleotide which encodes a mammalian GENSET polypeptide is introduced into a host cell to produce recombinant host cells. The recombinant host cells are then maintained under conditions appropriate for expression of the encoded mammalian GENSET polypeptide, whereby the nucleic acid is expressed. The compound to be assessed is added to the  
10 recombinant host cells; the resulting combination is referred to as a test sample. A detectable, GENSET polypeptide-associated property of the cells is detected. A control can be used in the methods of detecting agents which alter GENSET activity. For example, the control sample includes the same reagents but lacks the compound or agent being assessed; it is treated in the same manner as the test sample.

15

#### Methods of Screening for Compounds Modulating GENSET Expression and/or Activity

The present invention also relates to methods of screening compounds for their ability to modulate (e.g. increase or inhibit) the activity or expression of GENSET. More specifically, the present invention relates to methods of testing compounds for their ability either to increase or to  
20 decrease expression or activity of GENSET. The assays are performed *in vitro* or *in vivo*.

#### In vitro methods

*In vitro*, cells expressing GENSET polypeptides are incubated in the presence and absence of the test compound. By determining the level of GENSET expression in the presence of the test compound or the level of GENSET activity in the presence of the test compound, compounds can  
25 be identified that suppress or enhance GENSET expression or activity. Alternatively, constructs comprising a GENSET regulatory sequence operably linked to a reporter gene (e.g. luciferase, chloramphenicol acetyl transferase, LacZ, green fluorescent protein, etc.) can be introduced into host cells and the effect of the test compounds on expression of the reporter gene detected. Cells suitable for use in the foregoing assays include, but are not limited to, cells having the same origin  
30 as tissues or cell lines in which the polypeptide has been determined to be expressed by methods common to the art such as discussed herein. Consequently, the present invention encompasses a method for screening molecules that modulate the expression of a GENSET gene, said screening method comprising the steps of:

- a) cultivating a prokaryotic or an eukaryotic cell that has been transfected  
35 with a nucleotide sequence encoding a GENSET protein or a variant or a fragment thereof, placed under the control of its own promoter;
- b) bringing into contact said cultivated cell with a molecule to be tested;

- c) quantifying the expression of said GENSET protein or a variant or a fragment thereof in the presence of said molecule.

Using DNA recombination techniques well known by the one skill in the art, the GENSET protein encoding DNA sequence is inserted into an expression vector, downstream from its promoter sequence. As an illustrative example, the promoter sequence of the GENSET gene is contained in the 5' untranscribed region of the GENSET genomic DNA.

The quantification of the expression of a GENSET protein may be realized either at the mRNA level (using for example Northern blots, RT-PCR, preferably quantitative RT-PCR with primers and probes specific for the GENSET mRNA of interest) or at the protein level (using polyclonal or monoclonal antibodies in immunoassays such as ELISA or RIA assays, Western blots, or immunochemistry).

The present invention also concerns a method for screening substances or molecules that are able to increase, or in contrast to decrease, the level of expression of a GENSET gene. Such a method may allow the one skilled in the art to select substances exerting a regulating effect on the expression level of a GENSET gene and which may be useful as active ingredients included in pharmaceutical compositions for treating patients suffering from disorders associated with abnormal levels of GENSET products.

Thus, another part of the present invention is a method for screening a candidate molecule that modulates the expression of a GENSET gene, this method comprises the following steps:

- a) providing a recombinant cell host containing a nucleic acid, wherein said nucleic acid comprises a GENSET 5' regulatory region or a regulatory active fragment or variant thereof, operably linked to a polynucleotide encoding a detectable protein;
- b) obtaining a candidate molecule; and
- c) determining the ability of said candidate molecule to modulate the expression levels of said polynucleotide encoding the detectable protein.

In a further embodiment, said nucleic acid comprising a GENSET 5' regulatory region or a regulatory active fragment or variant thereof, includes the 5'UTR region of a GENSET cDNA selected from the group comprising of the 5'UTRs of the polynucleotide sequences of the Sequence Listing, those of human cDNA clone inserts of the deposited clone pool, regulatory active fragments, and variants thereof. In a more preferred embodiment of the above screening method, said nucleic acid includes a promoter sequence which is endogenous with respect to the GENSET 5'UTR sequence. In another more preferred embodiment of the above screening method, said nucleic acid includes a promoter sequence which is exogenous with respect to the GENSET 5'UTR sequence defined therein.

Preferred polynucleotides encoding a detectable protein are polynucleotides encoding beta galactosidase, green fluorescent protein (GFP) and chloramphenicol acetyl transferase (CAT).

The invention further relates to a method for the production of a pharmaceutical composition comprising a method of screening a candidate molecule that modulates the expression of a GENSET gene and furthermore mixing the identified molecule with a physiologically acceptable carrier.

- 5 The invention also pertains to kits for the screening of a candidate substance modulating the expression of a GENSET gene. Preferably, such kits comprise a recombinant vector that allows the expression of a GENSET 5' regulatory region or a regulatory active fragment or a variant thereof, operably linked to a polynucleotide encoding a detectable protein or a GENSET protein or a fragment or a variant thereof. More preferably, such kits include a recombinant vector
- 10 that comprises a nucleic acid including the 5'UTR region of a GENSET cDNA selected from the group comprising the 5'UTRs of the polynucleotide sequences of the Sequence Listing, those of human cDNA clone inserts of the deposited clone pool, regulatory active fragments and variants thereof, being operably linked to a polynucleotide encoding a detectable protein.

- For the design of suitable recombinant vectors useful for performing the screening
- 15 methods described above, it will be referred to the section of the present specification wherein the preferred recombinant vectors of the invention are detailed.

- Another object of the present invention comprises methods and kits for the screening of candidate substances that interact with a GENSET polypeptide, fragments or variants thereof. By their capacity to bind covalently or non-covalently to a GENSET protein, fragments or variants
- 20 thereof, these substances or molecules may be advantageously used both *in vitro* and *in vivo*.

*In vitro*, said interacting molecules may be used as detection means in order to identify the presence of a GENSET protein in a sample, preferably a biological sample.

A method for the screening of a candidate substance that interact with a GENSET polypeptide, fragments or variants thereof, said methods comprising the following steps:

- 25 a) providing a polypeptide comprising, consisting essentially of, or consisting of a GENSET protein or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide of the present invention;
- 30 b) obtaining a candidate substance;
- c) bringing into contact said polypeptide with said candidate substance;
- d) detecting the complexes formed between said polypeptide and said candidate substance.

- The invention further relates to a method for the production of a pharmaceutical
- 35 composition comprising a method for the screening of a candidate substance that interact with a GENSET polypeptide, fragments or variants thereof and furthermore mixing the identified substance with a physiologically acceptable carrier.

The invention further concerns a kit for the screening of a candidate substance interacting with the GENSET polypeptide, wherein said kit comprises:

- a) polypeptide comprising, consisting essentially of, or consisting of a GENSET protein or a fragment comprising a contiguous span of at least 6 amino acids, preferably at least 8 to 10 amino acids, more preferably at least 12, 15, 20, 25, 30, 40, 50, or 100 amino acids of a polypeptide of the present invention; and
- b) optionally means useful to detect the complex formed between said polypeptide or a variant thereof and the candidate substance.

In a preferred embodiment of the kit described above, the detection means comprises a monoclonal or polyclonal antibody binding to said GENSET protein or fragment or variant thereof.

#### In vivo methods

Compounds that suppress or enhance GENSET expression can also be identified using *in vivo* screens. In these assays, the test compound is administered (e.g. intravenously, intraperitoneally, intramuscularly, orally, or otherwise), to the animal, for example, at a variety of dose levels. The effect of the compound on GENSET expression is determined by comparing GENSET levels, for example in tissues known to express the gene of interest using Northern blots, immunoassays, PCR, etc., as described above. Suitable test animals include, but are not limited to, rodents (e.g., mice and rats), primates, and rabbits. Humanized mice can also be used as test animals, that is mice in which the endogenous mouse protein is ablated (knocked out) and the homologous human protein added back by standard transgenic approaches. Such mice express only the human form of a protein. Humanized mice expressing only the human GENSET can be used to study *in vivo* responses to potential agents regulating GENSET protein or mRNA levels. As an example, transgenic mice have been produced carrying the human apoE4 gene. They are then bred with a mouse line that lacks endogenous apoE, to produce an animal model carrying human proteins believed to be instrumental in development of Alzheimer's pathology. Such transgenic animals are useful for dissecting the biochemical and physiological steps of disease, and for development of therapies for disease intervention (Loring, *et al*, 1996) (incorporated herein by reference in its entirety).

#### **Uses for compounds modulating GENSET expression and/or biological activity**

Using *in vivo* (or *in vitro*) systems, it may be possible to identify compounds that exert a tissue specific effect, for example, that increase GENSET expression or activity only in tissues of interest, such as the adrenal gland, bone marrow, brain, cerebellum, colon, fetal brain, fetal kidney, fetal liver, heart, hypertrophic prostate, kidney, liver, lung, lymph ganglia, lymphocytes, muscle, ovary, pancreas, pituitary gland, placenta, prostate, salivary gland, spinal cord, spleen, stomach,

intestine, substantia nigra, testis, thyroid, umbilical cord, and uterus. Screening procedures such as those described above are also useful for identifying agents for their potential use in pharmacological intervention strategies. Agents that enhance GENSET gene expression or stimulate its activity may thus be used to induce any phenotype associated with a GENSET gene, or to treat disorders resulting from a deficiency of a GENSET polypeptide activity or expression. Compounds that suppress GENSET polypeptide expression or inhibit its activity can be used to treat any disease or condition associated with increased or deleterious GENSET polypeptide activity or expression.

Also encompassed by the present invention is an agent which interacts with a GENSET gene or polypeptide directly or indirectly, and inhibits or enhances GENSET polypeptide expression and/or function. In one embodiment, the agent is an inhibitor which interferes with a GENSET polypeptide directly (e.g., by binding the GENSET polypeptide) or indirectly (e.g., by blocking the ability of the GENSET polypeptide to have a GENSET biological activity). In a particular embodiment, an inhibitor of a GENSET protein is an antibody specific for the GENSET protein or a functional portion of the GENSET protein; that is, the antibody binds a GENSET polypeptide. For example, the antibody can be specific for a polypeptide encoded by one of the nucleic acid sequences of human GENSET nucleic acids, a mammalian GENSET nucleic acid, or portions thereof. Alternatively, the inhibitor can be an agent other than an antibody (e.g., small organic molecule, protein or peptide) which binds the GENSET polypeptide and blocks its activity. For example, the inhibitor can be an agent which mimics the GENSET polypeptide structurally, but lacks its function. Alternatively, it can be an agent which binds to or interacts with a molecule which the GENSET polypeptide normally binds to or interacts with, thus blocking the GENSET polypeptide from doing so and preventing it from exerting the effects it would normally exert.

In another embodiment, the agent is an enhancer (activator) of a GENSET polypeptide which increases the activity of the GENSET polypeptide (increases the effect of a given amount or level of GENSET), increases the length of time it is effective (by preventing its degradation or otherwise prolonging the time during which it is active) or both either directly or indirectly. For example, GENSET polynucleotides and polypeptides can be used to identify drugs which increase or decrease the ability of GENSET polypeptides to induce GENSET biological activity, which drugs are useful for the treatment or prevention of any disease or condition associated with a GENSET biological activity.

The GENSET sequences of the present invention can also be used to generate nonhuman gene knockout animals, such as mice, which lack a GENSET gene or transgenically overexpress a GENSET gene. For example, such GENSET gene knockout mice can be generated and used to obtain further insight into the function of the GENSET gene as well as assess the specificity of GENSET activators and inhibitors. Also, over expression of the GENSET gene (e.g., a human GENSET gene) in transgenic mice can be used as a means of creating a test system for GENSET

activators and inhibitors (e.g., against a human GENSET polypeptide). In addition, the GENSET gene can be used to clone the GENSET promoter/enhancer in order to identify regulators of GENSET gene transcription. GENSET gene knockout animals include animals which completely or partially lack the GENSET gene and/or GENSET activity or function. Thus the present invention relates to a method of inhibiting (partially or completely) a GENSET biological activity in a mammal (e.g., a human), the method comprising administering to the mammal an effective amount of an inhibitor of a GENSET polypeptide or polynucleotide. The invention also relates to a method of enhancing a GENSET biological activity in a mammal, the method comprising administering to the mammal an effective amount of an enhancer of a GENSET polypeptide or polynucleotide.

### **Inhibiting GENSET gene expression**

Therapeutic compositions according to the present invention may comprise advantageously one or several GENSET oligonucleotide fragments as an antisense tool or a triple helix tool that inhibits the expression of the corresponding GENSET gene.

#### Antisense Approach

In antisense approaches, nucleic acid sequences complementary to an mRNA are hybridized to the mRNA intracellularly, thereby blocking the expression of the protein encoded by the mRNA. The antisense nucleic acid molecules to be used in gene therapy may be either DNA or RNA sequences. Preferred methods using antisense polynucleotide according to the present invention are the procedures described by Sczakiel *et al.*, (1995) Trends Microbiol. 3(6):213-217, which disclosure is hereby incorporated by reference in its entirety.

Preferably, the antisense tools are chosen among the polynucleotides (15-200 bp long) that are complementary to GENSET mRNA, more preferably to the 5' end of the GENSET mRNA. In another embodiment, a combination of different antisense polynucleotides complementary to different parts of the desired targeted gene are used.

Other preferred antisense polynucleotides according to the present invention are sequences complementary to either a sequence of GENSET mRNAs comprising the translation initiation codon ATG or a sequence of GENSET genomic DNA containing a splicing donor or acceptor site. Preferably, the antisense polynucleotides of the invention have a 3' polyadenylation signal that has been replaced with a self-cleaving ribozyme sequence, such that RNA polymerase II transcripts are produced without poly(A) at their 3' ends, these antisense polynucleotides being incapable of export from the nucleus, such as described by Liu *et al.* (1994), Proc. Natl. Acad. Sci. USA. 91: 4528-4262, which disclosure is hereby incorporated by reference in its entirety. In a preferred embodiment, these GENSET antisense polynucleotides also comprise, within the ribozyme cassette, a histone stem-loop structure to stabilize cleaved transcripts against 3'-5' exonucleolytic degradation, such as the structure described by Eckner *et al.*, (1991) EMBO J. 10:3513-3522,

which disclosure is hereby incorporated by reference in its entirety.

The antisense nucleic acids should have a length and melting temperature sufficient to permit formation of an intracellular duplex having sufficient stability to inhibit the expression of the GENSET mRNA in the duplex. Strategies for designing antisense nucleic acids suitable for  
5 use in gene therapy are disclosed in Green *et al.*, (1986) Ann. Rev. Biochem. 55:569-597 and Izant and Weintraub, (1984) Cell 36(4):1007-15, the disclosures of which are incorporated herein by reference.

In some strategies, antisense molecules are obtained by reversing the orientation of the GENSET coding region with respect to a promoter so as to transcribe the opposite strand from that  
10 which is normally transcribed in the cell. The antisense molecules may be transcribed using *in vitro* transcription systems such as those which employ T7 or SP6 polymerase to generate the transcript. Another approach involves transcription of GENSET antisense nucleic acids *in vivo* by operably linking DNA containing the antisense sequence to a promoter in a suitable expression vector. Alternatively, oligonucleotides which are complementary to the strand normally  
15 transcribed in the cell may be synthesized *in vitro*. Thus, the antisense nucleic acids are complementary to the corresponding mRNA and are capable of hybridizing to the mRNA to create a duplex.

Specific examples of preferred antisense compounds useful in this invention include oligonucleotides containing modified backbones or non-natural internucleoside linkages. As  
20 defined in this specification, oligonucleotides having modified backbones include those that retain a phosphorus atom in the backbone and those that do not have a phosphorus atom in the backbone. For the purposes of this specification, and as sometimes referenced in the art, modified oligonucleotides that do not have a phosphorus atom in their internucleoside backbone can also be considered to be oligonucleosides.

25 Preferred modified oligonucleotide backbones include, for example, phosphorothioates, chiral phosphorothioates, phosphorodithioates, phosphotriesters, aminoalkylphosphotriesters, methyl and other alkyl phosphonates including 3'-alkylene phosphonates and chiral phosphonates, phosphinates, phosphoramidates including 3'-amino phosphoramidate and  
30 aminoalkylphosphoramidates, thionophosphoramidates, thionoalkylphosphonates, thionoalkylphosphotriesters, and boranophosphates having normal 3'-5' linkages, 2'-5' linked analogs of these, and those having inverted polarity wherein the adjacent pairs of nucleoside units are linked 3'-5' to 5'-3' or 2'-5' to 5'-2'. Various salts, mixed salts and free acid forms are also included.

Preferred modified oligonucleotide backbones that do not include a phosphorus atom  
35 therein have backbones that are formed by short chain alkyl or cycloalkyl internucleoside linkages, mixed heteroatom and alkyl or cycloalkyl internucleoside linkages, or one or more short chain heteroatomic or heterocyclic internucleoside linkages. These include those having morpholino

linkages (formed in part from the sugar portion of a nucleoside); siloxane backbones; sulfide, sulfoxide and sulfone backbones; formacetyl and thioformacetyl backbones; methylene formacetyl and thioformacetyl backbones; alkene containing backbones; sulfamate backbones; methyleneimino and methylenehydrazino backbones; sulfonate and sulfonamide backbones; amide backbones; and others having mixed N, O, S and CH.sub.2 component parts.

In other preferred oligonucleotide mimetics, both the sugar and the internucleoside linkage, i.e., the backbone, of the nucleotide units are replaced with novel groups. The base units are maintained for hybridization with an appropriate nucleic acid target compound. The such oligomeric compound, an oligonucleotide mimetic that has been shown to have excellent hybridization properties, is referred to as a peptide nucleic acid (PNA). In PNA compounds, the sugar-backbone of an oligonucleotide is replaced with an amide containing backbone, in particular an aminoethylglycine backbone. The nucleobases are retained and are bound directly or indirectly to aza nitrogen atoms of the amide portion of the backbone.

Oligonucleotides may also include nucleobase (often referred to in the art simply as "base") modifications or substitutions. As used herein, "unmodified" or "natural" nucleobases include the purine bases adenine (A) and guanine (G), and the pyrimidine bases thymine (T), cytosine (C) and uracil (U). Modified nucleobases include other synthetic and natural nucleobases such as 5-methylcytosine (5-me-C), 5-hydroxymethyl cytosine, xanthine, hypoxanthine, 2-aminoadenine, 6-methyl and other alkyl derivatives of adenine and guanine, 2-propyl and other alkyl derivatives of adenine and guanine, 2-thiouracil, 2-thiothymine and 2-thiocytosine, 5-halouracil and cytosine, 5-propynyl uracil and cytosine, 6-azo uracil, cytosine and thymine, 5-uracil (pseudouracil), 4-thiouracil, 8-halo, 8-amino, 8-thiol, 8-thioalkyl, 8-hydroxyl and other 8-substituted adenines and guanines, 5-halo particularly 5-bromo, 5-trifluoromethyl and other 5-substituted uracils and cytosines, 7-methylguanine and 7-methyladenine, 8-azaguanine and 8-azaadenine, 7-deazaguanine and 7-deazaadenine and 3-deazaguanine and 3-deazaadenine. Further nucleobases include those disclosed in U.S. Pat. No. 3,687,808, those disclosed in The Concise Encyclopedia Of Polymer Science And Engineering, pages 858-859, Kroschwitz, J. I., ed. John Wiley & Sons, 1990, those disclosed by Englisch et al., Angewandte Chemie, International Edition, 1991, 30, 613, and those disclosed by Sanghvi, Y. S., Chapter 15, Antisense Research and Applications, pages 289-302, Crooke, S. T. and Lebleu, B. ed., CRC Press, 1993. Certain of these nucleobases are particularly useful for increasing the binding affinity of the oligomeric compounds of the invention. These include 5-substituted pyrimidines, 6-azapyrimidines and N-2, N-6 and O-6 substituted purines, including 2-aminopropyladenine, 5-propynyluracil and 5-propynylcytosine. 5-methylcytosine substitutions have been shown to increase nucleic acid duplex stability by 0.6-1.2.degree. C. (Sanghvi, Y. S., Crooke, S. T. and Lebleu, B., eds., Antisense Research and Applications, CRC Press, Boca Raton, 1993, pp. 276-278) and are presently preferred base substitutions, even more particularly when combined with 2'-O-methoxyethyl sugar modifications

(U.S. Patent 6,242,590, hereby incorporated by reference).

Various types of antisense oligonucleotides complementary to the sequence of the GENSET cDNA or genomic DNA may be used. In one preferred embodiment, stable and semi-stable antisense oligonucleotides described in International Application No. PCT WO94/23026, hereby incorporated by reference, are used. In these molecules, the 3' end or both the 3' and 5' ends are engaged in intramolecular hydrogen bonding between complementary base pairs. These molecules are better able to withstand exonuclease attacks and exhibit increased stability compared to conventional antisense oligonucleotides.

In another preferred embodiment, the antisense oligodeoxynucleotides against herpes simplex virus types 1 and 2 described in International Application No. WO 95/04141, hereby incorporated by reference, are used.

In yet another preferred embodiment, the covalently cross-linked antisense oligonucleotides described in International Application No. WO 96/31523, hereby incorporated by reference, are used. These double- or single-stranded oligonucleotides comprise one or more, respectively, inter- or intra-oligonucleotide covalent cross-linkages, wherein the linkage consists of an amide bond between a primary amine group of one strand and a carboxyl group of the other strand or of the same strand, respectively, the primary amine group being directly substituted in the 2' position of the strand nucleotide monosaccharide ring, and the carboxyl group being carried by an aliphatic spacer group substituted on a nucleotide or nucleotide analog of the other strand or the same strand, respectively.

The antisense oligodeoxynucleotides and oligonucleotides disclosed in International Application No. WO 92/18522, incorporated by reference, may also be used. These molecules are stable to degradation and contain at least one transcription control recognition sequence which binds to control proteins and are effective as decoys therefor. These molecules may contain "hairpin" structures, "dumbbell" structures, "modified dumbbell" structures, "cross-linked" decoy structures and "loop" structures.

In another preferred embodiment, the cyclic double-stranded oligonucleotides described in European Patent Application No. 0 572 287 A2, hereby incorporated by reference are used. These ligated oligonucleotide "dumbbells" contain the binding site for a transcription factor and inhibit expression of the gene under control of the transcription factor by sequestering the factor.

Use of the closed antisense oligonucleotides disclosed in International Application No. WO 92/19732, hereby incorporated by reference, is also contemplated. Because these molecules have no free ends, they are more resistant to degradation by exonucleases than are conventional oligonucleotides. These oligonucleotides may be multifunctional, interacting with several regions which are not adjacent to the target mRNA.

Another modification of the oligonucleotides of the invention involves chemically linking to the oligonucleotide one or more moieties or conjugates which enhance the activity, cellular

- distribution or cellular uptake of the oligonucleotide. Such moieties include but are not limited to lipid moieties such as a cholesterol moiety (Letsinger et al., Proc. Natl. Acad. Sci. USA (1989) 86: 6553-6556), cholic acid (Manoharan et al., Bioorg. Med. Chem. Let. (1994) 4:1053-1060), a thioether, e.g., hexyl-S-tritylthiol (Manoharan et al., Ann. N.Y. Acad. Sci. (1992) 660:306-309;
- 5 Manoharan et al., Bioorg. Med. Chem. Let. (1993) 3:2765-2770), a thiocholesterol (Oberhauser et al., Nucl. Acids Res. (1992) 20:533-538), an aliphatic chain, e.g., dodecandiol or undecyl residues (Saison-Behmoaras et al., EMBO J. (1991) 10:1111-1118; Kabanov et al., FEBS Lett. (1990) 259: 327-330; Svinarchuk et al., Biochimie (1993) 75:49-54), a phospholipid, e.g., di-hexadecyl-rac-glycerol or triethylammonium 1,2-di-O-hexadecyl-rac-glycero-3-H-phosphonate (Manoharan et
- 10 al., Tetrahedron Lett., 1995, 36, 3651-3654; Shea et al., Nucl. Acids Res. (1990) 18:3777-3783), a polyamine or a polyethylene glycol chain (Manoharan et al., Nucleosides & Nucleotides (1995) 14: 969-973), or adamantane acetic acid (Manoharan et al., Tetrahedron Lett. (1995) 36:3651-3654), a palmityl moiety (Mishra et al., Biochim. Biophys. Acta (1995) 1264:229-237), or an octadecylamine or hexylamino-carbonyl-oxycholesterol moiety (Crooke et al., J. Pharmacol. Exp.
- 15 Ther. (1996) 277:923-937; U.S. Patent 6,242,590, which disclosures are hereby incorporated by reference in their entireties

- It is not necessary for all positions in a given compound to be uniformly modified, and in fact more than one of the aforementioned modifications may be incorporated in a single compound or even at a single nucleoside within an oligonucleotide. The present invention also includes
- 20 antisense compounds which are chimeric compounds. "Chimeric" antisense compounds or "chimeras," in the context of this invention, are antisense compounds, particularly oligonucleotides, which contain two or more chemically distinct regions, each made up of at least one monomer unit, i.e., a nucleotide in the case of an oligonucleotide compound. These oligonucleotides typically contain at least one region wherein the oligonucleotide is modified so as
- 25 to confer upon the oligonucleotide increased resistance to nuclease degradation, increased cellular uptake, and/or increased binding affinity for the target nucleic acid. An additional region of the oligonucleotide may serve as a substrate for enzymes capable of cleaving RNA:DNA or RNA:RNA hybrids. By way of example, RNase H is a cellular endonuclease which cleaves the RNA strand of an RNA:DNA duplex. Activation of RNase H, therefore, results in cleavage of the
- 30 RNA target, thereby greatly enhancing the efficiency of oligonucleotide inhibition of gene expression. Consequently, comparable results can often be obtained with shorter oligonucleotides when chimeric oligonucleotides are used, compared to phosphorothioate deoxyoligonucleotides hybridizing to the same target region. Cleavage of the RNA target can be routinely detected by gel electrophoresis and, if necessary, associated nucleic acid hybridization techniques known in the art
- 35 (U.S. Patent 6,242,590, hereby incorporated by reference).

Further included in the present invention is a method of high throughput screening of antisense nucleic acids and modified versions thereof for binding to targeted GENSET

polynucleotide sequences or fragments thereof. This method is directed toward determining optimally targeted sequences and/ or optimal species of targeting antisense molecules for binding. A preferred method comprises the steps of: contacting a random pool of test molecules with a set array of GENSET polynucleotide sequences or fragments thereof; detecting and quantifying

- 5 binding of test molecules to said array; and purification and identification of binding test molecules as discussed in U.S. Patent 6,022,691, which disclosure is hereby incorporated by reference.

Preferred test molecules are antisense oligonucleotides, oligonucleosides, and modified versions thereof as discussed herein. Further preferred test molecules are those that are capable of forming hydrogen bonds with GENSET polynucleotide sequences or fragments thereof.

- 10 The appropriate level of antisense nucleic acids required to inhibit gene expression may be determined using *in vitro* expression analysis. The antisense molecule may be introduced into the cells by diffusion, injection, infection or transfection using procedures known in the art. For example, the antisense nucleic acids can be introduced into the body as a bare or naked oligonucleotide, oligonucleotide encapsulated in lipid, oligonucleotide sequence encapsidated by
- 15 viral protein, or as an oligonucleotide operably linked to a promoter contained in an expression vector. The expression vector may be any of a variety of expression vectors known in the art, including retroviral or viral vectors, vectors capable of extrachromosomal replication, or integrating vectors. The vectors may be DNA or RNA.

- The antisense compounds of the invention encompass any physiologically acceptable salts, esters, or salts of such esters, or any other compound which, upon administration to an animal
- 20 including a human, is capable of providing (directly or indirectly) the biologically active metabolite or residue thereof. Accordingly, for example, the disclosure is also drawn to prodrugs and physiologically acceptable salts of the compounds of the invention, physiologically acceptable salts of such prodrugs, and other bioequivalents as discussed herein.

- 25 The antisense molecules are introduced onto cell samples at a number of different concentrations preferably between  $1 \times 10^{-10}$  M to  $1 \times 10^{-4}$  M. Once the minimum concentration that can adequately control gene expression is identified, the optimized dose is translated into a dosage suitable for use *in vivo*. For example, an inhibiting concentration in culture of  $1 \times 10^{-7}$  translates into a dose of approximately 0.6 mg/kg bodyweight. Levels of oligonucleotide approaching 100
- 30 mg/kg bodyweight or higher may be possible after testing the toxicity of the oligonucleotide in laboratory animals. It is additionally contemplated that cells from the vertebrate are removed, treated with the antisense oligonucleotide, and reintroduced into the vertebrate.

- In a preferred application of this invention, the polypeptide encoded by the gene is first identified, so that the effectiveness of antisense inhibition on translation can be monitored using
- 35 techniques that include but are not limited to antibody-mediated tests such as RIAs and ELISA, functional assays, or radiolabeling.

An alternative to the antisense technology that is used according to the present invention

comprises using ribozymes that will bind to a target sequence via their complementary polynucleotide tail and that will cleave the corresponding RNA by hydrolyzing its target site (namely "hammerhead ribozymes"). Briefly, the simplified cycle of a hammerhead ribozyme comprises (1) sequence specific binding to the target RNA via complementary antisense  
5 sequences; (2) site-specific hydrolysis of the cleavable motif of the target strand; and (3) release of cleavage products, which gives rise to another catalytic cycle. Indeed, the use of long-chain antisense polynucleotide (at least 30 bases long) or ribozymes with long antisense arms are advantageous. A preferred delivery system for antisense ribozyme is achieved by covalently linking these antisense ribozymes to lipophilic groups or to use liposomes as a convenient vector.  
10 Preferred antisense ribozymes according to the present invention are prepared as described by Rossi *et al.*, (1991) Pharmacol. Ther. 50:245-254 and Sczakiel *et al.* (1995), the specific preparation procedures being referred to in said articles being herein incorporated by reference.

#### Triple Helix Approach

The GENSET genomic DNA may also be used to inhibit the expression of the GENSET  
15 gene based on intracellular triple helix formation.

Triple helix oligonucleotides are used to inhibit transcription from a genome. They are particularly useful for studying alterations in cell activity when it is associated with a particular gene. The GENSET cDNAs or genomic DNAs of the present invention or, more preferably, a fragment of those sequences, can be used to inhibit gene expression in individuals having diseases  
20 associated with expression of a particular gene. Similarly, a portion of the GENSET genomic DNA can be used to study the effect of inhibiting GENSET gene transcription within a cell. Traditionally, homopurine sequences were considered the most useful for triple helix strategies. However, homopyrimidine sequences can also inhibit gene expression. Such homopyrimidine oligonucleotides bind to the major groove at homopurine:homopyrimidine sequences. Thus, both  
25 types of sequences from the GENSET genomic DNA are contemplated within the scope of this invention.

To carry out gene therapy strategies using the triple helix approach, the sequences of the GENSET genomic DNA are first scanned to identify 10-mer to 20-mer homopyrimidine or homopurine stretches which could be used in triple-helix based strategies for inhibiting GENSET  
30 expression. Following identification of candidate homopyrimidine or homopurine stretches, their efficiency in inhibiting GENSET expression is assessed by introducing varying amounts of oligonucleotides containing the candidate sequences into tissue culture cells which express the GENSET gene.

The oligonucleotides can be introduced into the cells using a variety of methods known to those  
35 skilled in the art, including but not limited to calcium phosphate precipitation, DEAE-Dextran, electroporation, liposome-mediated transfection or native uptake.

Treated cells are monitored for altered cell function or reduced GENSET expression using

techniques such as Northern blotting, RNase protection assays, or PCR based strategies to monitor the transcription levels of the GENSET gene in cells which have been treated with the oligonucleotide. The cell functions to be monitored are predicted based upon the homologies of the target gene corresponding to the cDNA from which the oligonucleotide was derived with

5 known gene sequences that have been associated with a particular function. The cell functions can also be predicted based on the presence of abnormal physiology within cells derived from individuals with a particular inherited disease, particularly when the cDNA is associated with the disease using techniques described in the section entitled "Identification of genes associated with hereditary diseases or drug response".

10 The oligonucleotides which are effective in inhibiting gene expression in tissue culture cells may then be introduced *in vivo* using the techniques and at a dosage calculated based on the *in vitro* results, as described in the section entitled "Antisense Approach".

In some embodiments, the natural (beta) anomers of the oligonucleotide units can be replaced with alpha anomers to render the oligonucleotide more resistant to nucleases. Further, an  
15 intercalating agent such as ethidium bromide, or the like, can be attached to the 3' end of the alpha oligonucleotide to stabilize the triple helix. For information on the generation of oligonucleotides suitable for triple helix formation. See Griffin *et al.*, (1989) Science 245:967-971, which is hereby incorporated by this reference.

## 20 **Treating GENSET gene-related disorders**

The present invention further relates to methods, uses of GENSET polypeptides and polynucleotides, and uses of modulators of GENSET polypeptides and polynucleotides, for treating diseases/disorders associated with GENSET genes by increasing or decreasing GENSET gene activity and/or expression. These methodologies can be effected using compounds selected  
25 using screening protocols such as those described herein and/or by using the gene therapy and antisense approaches described in the art and herein. Gene therapy can be used to effect targeted expression of GENSET genes in any tissue, e.g. a tissue associated with the disease or condition to be treated. The GENSET coding sequence can be cloned into an appropriate expression vector and targeted to a particular cell type(s) to achieve efficient, high level expression. Introduction of the  
30 GENSET coding sequence into target cells can be achieved, for example, using particle mediated DNA delivery, [Haynes *et al.*, (1996) J Biotechnol. 44(1-3):37-42 and Maurer *et al.*, (1999) Mol Membr Biol. 16(1):129-40], direct injection of naked DNA, [Levy *et al.*, (1996) Gene Ther. 3(3):201-11; and Felgner (1996) Hum Gene Ther. 7(15):1791-3], or viral vector mediated transport [Smith *et al.*, (1996) Antiviral Res. 32(2):99-115, Stone *et al.*, (2000) J Endocrinol. 164(2):103-18;  
35 Wu and Ataai (2000), Curr Opin Biotechnol. 11(2):205-8], each of which disclosures are hereby incorporated by reference in their entireties. Tissue specific effects can be achieved, for example, in the case of virus mediated transport by using viral vectors that are tissue specific, or by the use

of promoters that are tissue specific. For instance, any tissue-specific promoter may be used to achieve specific expression, for example albumin promoters (liver specific; Pinkert et al., 1987 Genes Dev. 1:268-277), lymphoid specific promoters (Calame et al., 1988 Adv. Immunol. 43:235-275), promoters of T-cell receptors (Winoto et al., 1989 EMBO J. 8:729-733) and

5 immunoglobulins (Banerji et al., 1983 Cell 33:729-740; Queen and Baltimore 1983 Cell 33:741-748), neuron-specific promoters (e.g. the neurofilament promoter; Byrne et al., 1989 Proc. Natl. Acad. Sci. USA 86:5473-5477), pancreas-specific promoters (Edlunch et al., 1985 Science 230:912-916) or mammary gland-specific promoters (milk whey promoter, U.S. Pat. No. 4,873,316 and European Application Publication No. 264, 166). Developmentally-regulated

10 promoters can also be used, such as the murine homeobox promoters (Kessel et al., 1990 Science 249:374-379) or the alpha-fetoprotein promoter (Campes et al., 1989 Genes Dev. 3:537-546).

Combinatorial approaches can also be used to ensure that the GENSET coding sequence is activated in the target tissue [Butt and Karathanasis (1995) Gene Expr. 4(6):319-36; Miller and Whelan, (1997) Hum Gene Ther. 8(7):803-15], which disclosures are hereby incorporated by

15 reference in their entireties. Antisense oligonucleotides complementary to GENSET mRNA can be used to selectively diminish or ablate the expression of the protein, for example, at sites of inflammation. More specifically, antisense constructs or antisense oligonucleotides can be used to inhibit the production of GENSET in high expressing cells such as determined by methods common to the art or discussed herein. Antisense mRNA can be produced by transfecting into

20 target cells an expression vector with the GENSET gene sequence, or a portion thereof, oriented in an antisense direction relative to the direction of transcription. Appropriate vectors include viral vectors, including retroviral, adenoviral, and adeno-associated viral vectors, as well as nonviral vectors. Tissue specific promoters can be used, as described supra. Alternatively, antisense oligonucleotides can be introduced directly into target cells to achieve the same goal. (See also

25 other delivery methodologies described herein in connection with gene therapy.). Oligonucleotides can be selected/designed to achieve a high level of specificity [Wagner, *et al.* (1996), Nat Biotechnol. 14(7):840-4], which disclosure is hereby incorporated by reference in its entirety. The therapeutic methodologies described herein are applicable to both human and non-human mammals (including cats and dogs).

30

#### **PHARMACEUTICAL AND PHYSIOLOGICALLY ACCEPTABLE COMPOSITIONS**

The present invention also relates to pharmaceutical or physiologically acceptable compositions comprising, as active agent, the polypeptides, nucleic acids or antibodies of the invention. The invention also relates to compositions comprising, as active agent, compounds

35 selected using the above-described screening protocols. Such compositions include the active agent in combination with a pharmaceutical or physiologically acceptable carriers such as a physiologically acceptable salt, ester, or salt of such esters. In the case of naked DNA, the

"carrier" may be gold particles. The amount of active agent in the composition can vary with the agent, the patient and the effect sought. Likewise, the dosing regimen can vary depending on the composition and the disease/disorder to be treated.

Therefore, the invention related to methods for the production of pharmaceutical composition comprising a method for selecting an active agent, compound, substance or molecule using any of the screening method described herein and furthermore mixing the identified active agent, compound, substance or molecule with a physiologically acceptable carrier.

The term "physiologically acceptable salts" refers to physiologically and pharmaceutically acceptable salts of the compounds of the invention: i.e., salts that retain the desired biological activity of the parent compound and do not impart undesired toxicological effects thereto. Physiologically acceptable base addition salts are formed with metals or amines, such as alkali and alkaline earth metals or organic amines. Examples of metals used as cations are sodium, potassium, magnesium, calcium, and the like. Examples of suitable amines are N,N'-dibenzylethylenediamine, chlorprocaine, choline, diethanolamine, dicyclohexylamine, ethylenediamine, N-methylglucamine, and procaine (see, for example, Berge et al., "Pharmaceutical Salts," J. of Pharma Sci. (1977) 66:1-19). The base addition salts of said acidic compounds are prepared by contacting the free acid form with a sufficient amount of the desired base to produce the salt in the conventional manner. The free acid form may be regenerated by contacting the salt form with an acid and isolating the free acid in the conventional manner. The free acid forms differ from their respective salt forms somewhat in certain physical properties such as solubility in polar solvents, but otherwise the salts are equivalent to their respective free acid for purposes of the present invention. As used herein, a "pharmaceutical addition salt" includes a physiologically acceptable salt of an acid form of one of the components of the compositions of the invention. These include organic or inorganic acid salts of the amines. Preferred acid salts are the hydrochlorides, acetates, salicylates, nitrates and phosphates. Other suitable physiologically acceptable salts are well known to those skilled in the art and include basic salts of a variety of inorganic and organic acids, such as, for example, with inorganic acids, such as for example hydrochloric acid, hydrobromic acid, sulfuric acid or phosphoric acid; with organic carboxylic, sulfonic, sulfo or phospho acids or N-substituted sulfamic acids, for example acetic acid, propionic acid, glycolic acid, succinic acid, maleic acid, hydroxymaleic acid, methylmaleic acid, fumaric acid, malic acid, tartaric acid, lactic acid, oxalic acid, gluconic acid, glucaric acid, glucuronic acid, citric acid, benzoic acid, cinnamic acid, mandelic acid, salicylic acid, 4-aminosalicylic acid, 2-phenoxybenzoic acid, 2-acetoxybenzoic acid, embonic acid, nicotinic acid or isonicotinic acid; and with amino acids, such as the 20 alpha-amino acids involved in the synthesis of proteins in nature, for example glutamic acid or aspartic acid, and also with phenylacetic acid, methanesulfonic acid, ethanesulfonic acid, 2-hydroxyethanesulfonic acid, ethane-1,2-disulfonic acid, benzenesulfonic acid, 4-methylbenzenesulfonic acid, naphthalene-2-sulfonic acid, naphthalene-1,5-disulfonic acid, 2- or 3-

phosphoglycerate, glucose-6-phosphate, N-cyclohexylsulfamic acid (with the formation of cyclamates), or with other acid organic compounds, such as ascorbic acid. Physiologically acceptable salts of compounds may also be prepared with a physiologically acceptable cation. Suitable physiologically acceptable cations are well known to those skilled in the art and include

5 alkaline, alkaline earth, ammonium and quaternary ammonium cations. Carbonates or hydrogen carbonates are also possible. For oligonucleotides, preferred examples of physiologically acceptable salts include but are not limited to (a) salts formed with cations such as sodium, potassium, ammonium, magnesium, calcium, polyamines such as spermine and spermidine, etc.; (b) acid addition salts formed with inorganic acids, for example hydrochloric acid, hydrobromic

10 acid, sulfuric acid, phosphoric acid, nitric acid and the like; (c) salts formed with organic acids such as, for example, acetic acid, oxalic acid, tartaric acid, succinic acid, maleic acid, fumaric acid, gluconic acid, citric acid, malic acid, ascorbic acid, benzoic acid, tannic acid, palmitic acid, alginic acid, polyglutamic acid, naphthalenesulfonic acid, methanesulfonic acid, p-toluenesulfonic acid, naphthalenedisulfonic acid, polygalacturonic acid, and the like; and (d) salts formed from

15 elemental anions such as chlorine, bromine, and iodine.

The term "prodrug" indicates a therapeutic agent that is prepared in an inactive form that is converted to an active form (i.e., drug) within the body or cells thereof by the action of endogenous enzymes or other chemicals and/or conditions. In particular, prodrug versions of the oligonucleotides of the invention are prepared as SATE [(S-acetyl-2-thioethyl) phosphate]

20 derivatives according to the methods disclosed in WO 93/24510 to Gosselin et al., published Dec. 9, 1993 or in WO 94/26764 and U.S. Pat. No. 5,770,713 to Imbach, et al.

The pharmaceutical compositions utilized in this invention may be administered by any number of routes including, but not limited to: parenteral, intracranial, intraorbital, intracapsular, intraspinal, intracisternal, intrapulmonary, oral, intravenous, intramuscular, intra-arterial,

25 intramedullary, intrathecal, intraventricular, transdermal, subcutaneous, intraperitoneal, intranasal, enteral, topical, sublingual, or rectal means. In addition to the active ingredients, these pharmaceutical compositions may contain suitable physiologically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. Further details on techniques for formulation and

30 administration may be found in the latest edition of Remington's Pharmaceutical Sciences (Maack Publishing Co. Easton, Pa).

Pharmaceutical compositions for oral administration can be formulated using physiologically acceptable carriers well known in the art in dosages suitable for oral administration. Such carriers enable the pharmaceutical compositions to be formulated as

35 powders, tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions, and the like, for ingestion by the patient.

Pharmaceutical preparations for oral use can be obtained through combining active

compounds with solid excipient, optionally grinding the resulting mixture,, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients are carbohydrate or protein fillers, such as sugars, including lactose, sucrose, mannitol, or sorbitol; starch from corn, wheat, rice, potato, or other plants; cellulose, such as methyl cellulose, hydroxypropylmethyl-cellulose, or sodium carboxymethylcellulose; gums including arabic and tragacanth; and proteins such as gelatin and collagen. If desired, disintegrating or solubilizing agents may be added, such as the cross-linked polyvinyl pyrrolidone, agar, alginic acid, or a salt thereof, such as sodium alginate.

Dragee cores may be used in conjunction with suitable coatings, such as concentrated sugar solutions, which may also contain gum arabic, talc, polyvinylpyrrolidone, carbopol gel, polyethylene glycol, and/or titaniumdioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for product identification or to characterize the quantity of active compound, i.e., dosage.

Pharmaceutical preparations which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a coating, such as glycerol or sorbitol. Push-fit capsules can contain active ingredients mixed with a filler or binders, such as lactose or starches, lubricants, such as talc or magnesium stearate, and, optionally, stabilizers. In soft capsules, the active compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid, or liquidpolyethylene glycol with or without stabilizers.

Formulations suitable for pulmonary or respiratory delivery include dry powders, liquid solutions or suspensions suitable for nebulization, and propellant formulations suitable for use in metered dose inhalers (MDI's). The preparation of such formulations is well described in the patent, scientific, and medical literatures, and the following descriptions are intended to be exemplary only.

Dry powder formulations will have a particle size within a preferred range for deposition within the alveolar region of the lung, typically from 0.5 .mu.m to 5 .mu.m. Respirable powders of pharmaceutical compositions within the preferred size range can be produced by a variety of conventional techniques, such as jet-milling, spray-drying, solvent precipitation, and the like. Dry powders can then be administered to the patient in conventional dry powder inhalers (DPI's) that use the patient's inspiratory breath through the device to disperse the powder or in air-assisted devices that use an external power source to disperse the powder into an aerosol cloud, as described in U.S. Pat. No. 5,458,135, the full disclosure of which is incorporated herein by reference.

Dry powder devices typically require a powder mass in the range from about 1 mg to 10 mg to produce a single aerosolized dose, which may necessitate addition of a dry bulking powder to the pharmaceutical formulation. Preferred dry bulking powders include sucrose, lactose, trehalose, human serum albumin (HSA), and glycine. Other suitable dry bulking powders include

cellobiose, dextrans, maltotriose, pectin, sodium citrate, sodium ascorbate, mannitol, and the like. Furthermore, stabilizing buffers and salts may be used. Other additives, such as chelating agents, peptidase inhibitors, and the like, which would facilitate the biological activity of the pharmaceutical composition once it is dissolved within the lung would be appropriate. For  
5 example, ethylenediaminetetraacetic acid (ETDA) would be useful as a chelator for divalent cations which are peptidase cofactors.

Liquid formulations for use in nebulizer systems preferably employ slightly acidic buffers (pH 4-6) such as acetate, ascorbate, and citrate, at concentrations of 5 mM to 50 mM. These buffers can act as antioxidants. Physiologically acceptable components to enhance or maintain  
10 chemical stability include: antioxidants, chelating agents, protease inhibitors, isotonic modifiers, inert gases, and the like. A preferred type of nebulizer suitable for delivering such liquid formulations is described in U.S. Pat. No. 5,458,135, the disclosure of which is incorporated herein by reference.

For use in MDI's, the pharmaceutical composition will be dissolved or suspended in a  
15 suitable aerosol propellant, such as a chlorofluorocarbon (CFC) or a hydrofluorocarbon (HFC). Suitable CFC's include trichloromonofluoromethane (propellant 11), dichlorotetrafluoromethane (propellant 114), and dichlorodifluoromethane (propellant 12). Suitable HFC's include tetrafluoroethane (HFC-134a) and heptafluoropropane (HFC-227).

Preferably, for incorporation into the aerosol propellant, the pharmaceutical composition  
20 will be processed into respirable particles as described for the dry powder formulations. The particles are then suspended in the propellant, typically being coated with a surfactant to enhance their dispersion. Suitable surfactants include oleic acid, sorbitan trioleate, and various long chain diglycerides and phospholipids. Such aerosol propellant formulations may further include a lower alcohol, such as ethanol (up to 30% by weight) and other additives to maintain or enhance  
25 chemical stability and physiological acceptability (U.S. Patent 6,080,721, which disclosure is hereby incorporated by reference in its entirety).

For topical or nasal administration, penetrants appropriate to the particular barrier to be permeated are used in the formulation. Such penetrants are generally known in the art.

Pharmaceutical formulations suitable for parenteral administration may be formulated in  
30 aqueous solutions, preferably in physiologically compatible buffers such as Hanks solution, Ringer's solution, or physiologically buffered saline. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethylcellulose, sorbitol, or dextran. Additionally, suspensions of the active compounds may be prepared as appropriate oily injection suspensions. Suitable lipophilic solvents or vehicles include fatty oils  
35 such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes. Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

The pharmaceutical compositions of the present invention may be manufactured in a manner that is known in the art, e.g., by means of conventional mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping, or lyophilizing processes.

The pharmaceutical composition may be provided as a salt and can be formed with many acids, including but not limited to, hydrochloric, sulfuric, acetic, lactic, tartaric, malic, succinic, etc. Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free base forms. In other cases, the preferred preparation may be a lyophilized powder which may contain any or all of the following: 1-50 mM histidine, 0.1%-2% sucrose, and 2-7% mannitol, at a pH range of 4.5 to 5.5, that is combined with buffer prior to use.

10 After pharmaceutical compositions have been prepared, they can be placed in an appropriate container and labeled for treatment of an indicated condition. For administration of a GENSET polypeptide, such labeling would include amount, frequency, and method of administration.

Pharmaceutical compositions suitable for use in the invention include compositions wherein the 15 active ingredients are contained in an effective amount to achieve the intended purpose. The determination of an effective dose is well within the capability of those skilled in the art.

For any compound, the therapeutically effective dose can be estimated initially either in cell culture assays, e.g., of neoplastic cells, or in animal models, usually mice, rabbits, dogs, or pigs. The animal model may also be used to determine the appropriate concentration range and 20 route of administration. Such information can then be used to determine useful doses and routes for administration in humans.

A therapeutically effective dose refers to that amount of active ingredient, for example a GENSET polypeptide or fragments thereof, antibodies specific to GENSET polypeptides, agonists, antagonists or inhibitors of GENSET polypeptides, which ameliorates the symptoms or condition. 25 Therapeutic efficacy and toxicity may be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., ED50 (the dose therapeutically effective in 50% of the population) and LD50 (the dose lethal to 50% of the population). The dose ratio between therapeutic and toxic effects is the therapeutic index, and it can be expressed as the ratio, LD50/ED50. Pharmaceutical compositions which exhibit large therapeutic indices are preferred. 30 The data obtained from cell culture assays and animal studies is used in formulating a range of dosage for human use. The dosage contained in such compositions is preferably within a range of circulating concentrations that include the ED50 with little or no toxicity. The dosage varies within this range depending upon the dosage form employed, sensitivity of the patient, and the route of administration.

35 The exact dosage will be determined by the practitioner, in light of factors related to the subject that requires treatment. Dosage and administration are adjusted to provide sufficient levels of the active moiety or to maintain the desired effect. Factors which may be taken into account

include the severity of the disease state, general health of the subject, age, weight, and gender of the subject, diet, time and frequency of administration, drug combination(s), reaction sensitivities, and tolerance/response to therapy. Other factors that may be considered when evaluating the proper dosage include the chemical nature of the compound destined for delivery, the biological responses associated with the compound (both intended and coincidental) and anticipated contraindications. Additionally, the mode of delivery (including but not limited to systemic and/or local applications: oral, oral enteric, intramuscular injection, subcutaneous injection, intradermal injection, interarticular space, intravascular injection, intravenous infusion, suppository, topical preparation, transdermal system), the duration and frequency of administration (e.g.  $n$  doses per hours,  $n$  doses per day,  $n$  doses per week, cumulative dosage per day, cumulative dosage per week), the biologically effective dose delivered to target site, often indicated by plasma level concentrations, and the rate or efficiency of compound clearance from the body may be considered. Long-acting pharmaceutical compositions maybe administered every 3 to 4 days, every week, or once every two weeks depending on half-life and clearance rate of the particular formulation.

Normal dosage amounts may vary depending upon the route of administration. Guidance as to particular dosages and methods of delivery is provided in the literature and generally available to practitioners in the art. Those skilled in the art will employ different formulations for nucleotides than for proteins or their inhibitors. Similarly, delivery of polynucleotides or polypeptides will be specific to particular cells, conditions, locations, etc. In general, for a 75kg individual the normal dosage range are as follows: for a small molecule compound an effective dose is usually between 0.3–50 mg/kg; for recombinant polypeptides an effective dose is usually between 0.25–7.5 mg/kg; for compounds used for mediating humoral immune responses (e.g., polyvalent pneumococcal vaccine, Rh<sub>0</sub> (D) immune globulin, Hepatitis B vaccine, anti-CD20 antigen) the effective dose is usually between 0.0015–1.5 mg/kg; for hormone supplemental compounds (e.g. estradiol, norethindrone) the effective dose is usually between 0.0005–0.5 mg/kg depending upon delivery system utilized (e.g. transdermal, oral, topical).

Transdermal delivery systems (e.g. estradiol transdermal system, transdermal scopolamine system, transdermal nicotine patch) must be calibrated for nominal delivery dosages based upon efficiency of percutaneous delivery for the individual and specific compounds, surface area (cm<sup>2</sup>) of transdermal system contact, quantity and form of compound integrated into transdermal delivery system and anatomical location of positioned transdermal system. The effective dosage range of compounds administered in this manner is usually between 0.005–0.5 mg/kg

35

#### USES OF GENSET SEQUENCES: COMPUTER-RELATED EMBODIMENTS

As used herein the term “GENSET cDNAs” encompasses the nucleotide sequences of the

present invention.

It will be appreciated by those skilled in the art that the nucleic acid codes of the invention and polypeptide codes of the invention can be stored, recorded, and manipulated on any medium which can be read and accessed by a computer. As used herein, the words "recorded" and "stored" refer to a process for storing information on a computer medium. A skilled artisan can readily adopt any of the presently known methods for recording information on a computer readable medium to generate manufactures comprising one or more of the nucleic acid codes of the invention, or one or more of the polypeptide codes of the invention. Another aspect of the present invention is a computer readable medium having recorded thereon at least 1, 2, 5, 10, 15, 20, 25, 30, or 50 nucleic acid codes of the invention. Another aspect of the present invention is a computer readable medium having recorded thereon at least 1, 2, 5, 10, 15, 20, 25, 30, or 50 polypeptide codes of the invention.

Computer readable media include magnetically readable media, optically readable media, electronically readable media and magnetic/optical media. For example, the computer readable media may be a hard disk, a floppy disk, a magnetic tape, CD-ROM, Digital Versatile Disk (DVD), Random Access Memory (RAM), or Read Only Memory (ROM) as well as other types of other media known to those skilled in the art.

Embodiments of the present invention include systems, particularly computer systems which store and manipulate the sequence information described herein. One example of a computer system 100 is illustrated in block diagram form in Figure 1. As used herein, "a computer system" refers to the hardware components, software components, and data storage components used to analyze the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. In one embodiment, the computer system 100 is a Sun Enterprise 1000 server (Sun Microsystems, Palo Alto, CA). The computer system 100 preferably includes a processor for processing, accessing and manipulating the sequence data. The processor 105 can be any well-known type of central processing unit, such as the Pentium III from Intel Corporation, or similar processor from Sun, Motorola, Compaq or International Business Machines.

Preferably, the computer system 100 is a general purpose system that comprises the processor 105 and one or more internal data storage components 110 for storing data, and one or more data retrieving devices for retrieving the data stored on the data storage components. A skilled artisan can readily appreciate that any one of the currently available computer systems are suitable.

In one particular embodiment, the computer system 100 includes a processor 105 connected to a bus which is connected to a main memory 115 (preferably implemented as RAM) and one or more internal data storage devices 110, such as a hard drive and/or other computer readable media having data recorded thereon. In some embodiments, the computer system 100

further includes one or more data retrieving device 118 for reading the data stored on the internal data storage devices 110.

The data retrieving device 118 may represent, for example, a floppy disk drive, a compact disk drive, a magnetic tape drive, etc. In some embodiments, the internal data storage device 110 is a removable computer readable medium such as a floppy disk, a compact disk, a magnetic tape, etc. containing control logic and/or data recorded thereon. The computer system 100 may advantageously include or be programmed by appropriate software for reading the control logic and/or the data from the data storage component once inserted in the data retrieving device.

The computer system 100 includes a display 120 which is used to display output to a computer user. It should also be noted that the computer system 100 can be linked to other computer systems 125a-c in a network or wide area network to provide centralized access to the computer system 100.

Software for accessing and processing the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention (such as search tools, compare tools, and modeling tools etc.) may reside in main memory 115 during execution.

In some embodiments, the computer system 100 may further comprise a sequence comparer for comparing the above-described nucleic acid codes of the invention or the polypeptide codes of the invention stored on a computer readable medium to reference nucleotide or polypeptide sequences stored on a computer readable medium. A "sequence comparer" refers to one or more programs which are implemented on the computer system 100 to compare a nucleotide or polypeptide sequence with other nucleotide or polypeptide sequences and/or compounds including but not limited to peptides, peptidomimetics, and chemicals stored within the data storage means. For example, the sequence comparer may compare the nucleotide sequences of nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention stored on a computer readable medium to reference sequences stored on a computer readable medium to identify homologies, motifs implicated in biological function, or structural motifs. The various sequence comparer programs identified elsewhere in this patent specification are particularly contemplated for use in this aspect of the invention.

Figure 2 is a flow diagram illustrating one embodiment of a process 200 for comparing a new nucleotide or protein sequence with a database of sequences in order to determine the homology levels between the new sequence and the sequences in the database. The database of sequences can be a private database stored within the computer system 100, or a public database such as GENBANK, PIR OR SWISSPROT that is available through the Internet.

The process 200 begins at a start state 201 and then moves to a state 202 wherein the new sequence to be compared is stored to a memory in a computer system 100. As discussed above, the memory could be any type of memory, including RAM or an internal storage device.

The process 200 then moves to a state 204 wherein a database of sequences is opened for

analysis and comparison. The process 200 then moves to a state 206 wherein the first sequence stored in the database is read into a memory on the computer. A comparison is then performed at a state 210 to determine if the first sequence is the same as the second sequence. It is important to note that this step is not limited to performing an exact comparison between the new sequence and the first sequence in the database. Well-known methods are known to those of skill in the art for comparing two nucleotide or protein sequences, even if they are not identical. For example, gaps can be introduced into one sequence in order to raise the homology level between the two tested sequences. The parameters that control whether gaps or other features are introduced into a sequence during comparison are normally entered by the user of the computer system.

10        Once a comparison of the two sequences has been performed at the state 210, a determination is made at a decision state 210 whether the two sequences are the same. Of course, the term "same" is not limited to sequences that are absolutely identical. Sequences that are within the homology parameters entered by the user will be marked as "same" in the process 200.

15        If a determination is made that the two sequences are the same, the process 200 moves to a state 214 wherein the name of the sequence from the database is displayed to the user. This state notifies the user that the sequence with the displayed name fulfills the homology constraints that were entered. Once the name of the stored sequence is displayed to the user, the process 200 moves to a decision state 218 wherein a determination is made whether more sequences exist in the database. If no more sequences exist in the database, then the process 200 terminates at an end state 220. However, if more sequences do exist in the database, then the process 200 moves to a state 224 wherein a pointer is moved to the next sequence in the database so that it can be compared to the new sequence. In this manner, the new sequence is aligned and compared with every sequence in the database.

25        It should be noted that if a determination had been made at the decision state 212 that the sequences were not homologous, then the process 200 would move immediately to the decision state 218 in order to determine if any other sequences were available in the database for comparison.

30        Accordingly, one aspect of the present invention is a computer system comprising a processor, a data storage device having stored thereon a nucleic acid code of the invention or a polypeptide code of the invention, a data storage device having retrievably stored thereon reference nucleotide sequences or polypeptide sequences to be compared to the nucleic acid code of the invention or polypeptide code of the invention and a sequence comparer for conducting the comparison. The sequence comparer may indicate a homology level between the sequences compared or identify motifs implicated in biological function and structural motifs in the nucleic acid code of the invention and polypeptide codes of the invention or it may identify structural motifs in sequences which are compared to these nucleic acid codes and polypeptide codes. In some embodiments, the data storage device may have stored thereon the sequences of at least 2, 5,

10, 15, 20, 25, 30, or 50 of the nucleic acid codes of the invention or polypeptide codes of the invention.

Another aspect of the present invention is a method for determining the level of homology between a nucleic acid code of the invention and a reference nucleotide sequence, comprising the steps of reading the nucleic acid code and the reference nucleotide sequence through the use of a computer program which determines homology levels and determining homology between the nucleic acid code and the reference nucleotide sequence with the computer program. The computer program may be any of a number of computer programs for determining homology levels, including those specifically enumerated herein, including BLAST2N with the default parameters or with any modified parameters. The method may be implemented using the computer systems described above. The method may also be performed by reading 2, 5, 10, 15, 20, 25, 30, or 50 of the above described nucleic acid codes of the invention through the use of the computer program and determining homology between the nucleic acid codes and reference nucleotide sequences.

Figure 3 is a flow diagram illustrating one embodiment of a process 250 in a computer for determining whether two sequences are homologous. The process 250 begins at a start state 252 and then moves to a state 254 wherein a first sequence to be compared is stored to a memory. The second sequence to be compared is then stored to a memory at a state 256. The process 250 then moves to a state 260 wherein the first character in the first sequence is read and then to a state 262 wherein the first character of the second sequence is read. It should be understood that if the sequence is a nucleotide sequence, then the character would normally be either A, T, C, G or U. If the sequence is a protein sequence, then it should be in the single letter amino acid code so that the first and sequence sequences can be easily compared.

A determination is then made at a decision state 264 whether the two characters are the same. If they are the same, then the process 250 moves to a state 268 wherein the next characters in the first and second sequences are read. A determination is then made whether the next characters are the same. If they are, then the process 250 continues this loop until two characters are not the same. If a determination is made that the next two characters are not the same, the process 250 moves to a decision state 274 to determine whether there are any more characters either sequence to read.

If there are no more characters to read, then the process 250 moves to a state 276 wherein the level of homology between the first and second sequences is displayed to the user. The level of homology is determined by calculating the proportion of characters between the sequences that were the same out of the total number of sequences in the first sequence. Thus, if every character in a first 100 nucleotide sequence aligned with a every character in a second sequence, the homology level would be 100%.

Alternatively, the computer program may be a computer program which compares the

nucleotide sequences of the nucleic acid codes of the present invention, to reference nucleotide sequences in order to determine whether the nucleic acid code of the invention differs from a reference nucleic acid sequence at one or more positions. Optionally such a program records the length and identity of inserted, deleted or substituted nucleotides with respect to the sequence of  
5 either the reference polynucleotide or the nucleic acid code of the invention. In one embodiment, the computer program may be a program which determines whether the nucleotide sequences of the nucleic acid codes of the invention contain one or more single nucleotide polymorphisms (SNP) with respect to a reference nucleotide sequence. These single nucleotide polymorphisms may each comprise a single base substitution, insertion, or deletion.

10 Another aspect of the present invention is a method for determining the level of homology between a polypeptide code of the invention and a reference polypeptide sequence, comprising the steps of reading the polypeptide code of the invention and the reference polypeptide sequence through use of a computer program which determines homology levels and determining homology between the polypeptide code and the reference polypeptide sequence using the computer program.

15 Accordingly, another aspect of the present invention is a method for determining whether a nucleic acid code of the invention differs at one or more nucleotides from a reference nucleotide sequence comprising the steps of reading the nucleic acid code and the reference nucleotide sequence through use of a computer program which identifies differences between nucleic acid sequences and identifying differences between the nucleic acid code and the reference nucleotide  
20 sequence with the computer program. In some embodiments, the computer program is a program which identifies single nucleotide polymorphisms. The method may be implemented by the computer systems described above and the method illustrated in Figure 3. The method may also be performed by reading at least 2, 5, 10, 15, 20, 25, 30, or 50 of the nucleic acid codes of the invention and the reference nucleotide sequences through the use of the computer program and  
25 identifying differences between the nucleic acid codes and the reference nucleotide sequences with the computer program.

In other embodiments the computer based system may further comprise an identifier for identifying features within the nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. An "identifier" refers to one  
30 or more programs which identifies certain features within the above-described nucleotide sequences of the nucleic acid codes of the invention or the amino acid sequences of the polypeptide codes of the invention. In one embodiment, the identifier may comprise a program which identifies an open reading frame in the cDNAs codes of the invention.

Figure 4 is a flow diagram illustrating one embodiment of an identifier process 300 for  
35 detecting the presence of a feature in a sequence. The process 300 begins at a start state 302 and then moves to a state 304 wherein a first sequence that is to be checked for features is stored to a memory 115 in the computer system 100. The process 300 then moves to a state 306 wherein a

database of sequence features is opened. Such a database would include a list of each feature's attributes along with the name of the feature. For example, a feature name could be "Initiation Codon" and the attribute would be "ATG". Another example would be the feature name "TAATAA Box" and the feature attribute would be "TAATAA". An example of such a database  
5 is produced by the University of Wisconsin Genetics Computer Group ([www.gcg.com](http://www.gcg.com)).

Once the database of features is opened at the state 306, the process 300 moves to a state 308 wherein the first feature is read from the database. A comparison of the attribute of the first feature with the first sequence is then made at a state 310. A determination is then made at a decision state 316 whether the attribute of the feature was found in the first sequence. If the  
10 attribute was found, then the process 300 moves to a state 318 wherein the name of the found feature is displayed to the user.

The process 300 then moves to a decision state 320 wherein a determination is made whether more features exist in the database. If no more features do exist, then the process 300 terminates at an end state 324. However, if more features do exist in the database, then the process  
15 300 reads the next sequence feature at a state 326 and loops back to the state 310 wherein the attribute of the next feature is compared against the first sequence.

It should be noted, that if the feature attribute is not found in the first sequence at the decision state 316, the process 300 moves directly to the decision state 320 in order to determine if any more features exist in the database.

20 In another embodiment, the identifier may comprise a molecular modeling program which determines the 3-dimensional structure of the polypeptides codes of the invention. Such programs may use any methods known to those skilled in the art including methods based on homology-modeling, fold recognition and *ab initio* methods as described in Sternberg *et al.*, (1999) Curr Opin Struct Biol. 9(3):368-73, which disclosure is hereby incorporated by reference in its entirety. In  
25 some embodiments, the molecular modeling program identifies target sequences that are most compatible with profiles representing the structural environments of the residues in known three-dimensional protein structures. (See, e.g., Eisenberg *et al.*, U.S. Patent No. 5,436,850 issued July 25, 1995, which disclosure is hereby incorporated by reference in its entirety). In another technique, the known three-dimensional structures of proteins in a given family are superimposed  
30 to define the structurally conserved regions in that family. This protein modeling technique also uses the known three-dimensional structure of a homologous protein to approximate the structure of the polypeptide codes of the invention. (See e.g., Srinivasan, *et al.*, U.S. Patent No. 5,557,535 issued September 17, 1996, which disclosure is hereby incorporated by reference in its entirety). Conventional homology modeling techniques have been used routinely to build models of  
35 proteases and antibodies. [Sowdhamini *et al.* (1997), Protein Engineering 10:207, 215]. Comparative approaches can also be used to develop three-dimensional protein models when the protein of interest has poor sequence identity to template proteins. In some cases, proteins fold

into similar three-dimensional structures despite having very weak sequence identities. For example, the three-dimensional structures of a number of helical cytokines fold in similar three-dimensional topology in spite of weak sequence homology.

The recent development of threading methods now enables the identification of likely folding patterns in a number of situations where the structural relatedness between target and template(s) is not detectable at the sequence level. Hybrid methods, in which fold recognition is performed using Multiple Sequence Threading (MST), structural equivalencies are deduced from the threading output using a distance geometry program DRAGON to construct a low resolution model, and a full-atom representation is constructed using a molecular modeling package such as QUANTA.

According to this 3-step approach, candidate templates are first identified by using the novel fold recognition algorithm MST, which is capable of performing simultaneous threading of multiple aligned sequences onto one or more 3-D structures. In a second step, the structural equivalencies obtained from the MST output are converted into interresidue distance restraints and fed into the distance geometry program DRAGON, together with auxiliary information obtained from secondary structure predictions. The program combines the restraints in an unbiased manner and rapidly generates a large number of low resolution model confirmations. In a third step, these low resolution model confirmations are converted into full-atom models and subjected to energy minimization using the molecular modeling package QUANTA. (See e.g., Aszódi *et al.*, (1997) Proteins: Structure, Function, and Genetics, Supplement 1:38-42).

The results of the molecular modeling analysis may then be used in rational drug design techniques to identify agents which modulate the activity of the polypeptide codes of the invention.

Accordingly, another aspect of the present invention is a method of identifying a feature within the nucleic acid codes of the invention or the polypeptide codes of the invention comprising reading the nucleic acid code(s) or the polypeptide code(s) through the use of a computer program which identifies features therein and identifying features within the nucleic acid code(s) or polypeptide code(s) with the computer program. In one embodiment, computer program comprises a computer program which identifies open reading frames. In a further embodiment, the computer program identifies linear or structural motifs in a polypeptide sequence. In another embodiment, the computer program comprises a molecular modeling program. The method may be performed by reading a single sequence or at least 2, 5, 10, 15, 20, 25, 30, or 50 of the nucleic acid codes of the invention or the polypeptide codes of the invention through the use of the computer program and identifying features within the nucleic acid codes or polypeptide codes with the computer program.

The nucleic acid codes of the invention or the polypeptide codes of the invention may be stored and manipulated in a variety of data processor programs in a variety of formats. For example, they may be stored as text in a word processing file, such as MicrosoftWORD or

WORDPERFECT or as an ASCII file in a variety of database programs familiar to those of skill in the art, such as DB2, SYBASE, or ORACLE. In addition, many computer programs and databases may be used as sequence comparers, identifiers, or sources of reference nucleotide or polypeptide sequences to be compared to the nucleic acid codes of the invention or the polypeptide codes of the invention. The following list is intended not to limit the invention but to provide guidance to programs and databases which are useful with the nucleic acid codes of the invention or the polypeptide codes of the invention. The programs and databases which may be used include, but are not limited to: MacPattern (EMBL), DiscoveryBase (Molecular Applications Group), GeneMine (Molecular Applications Group), Look (Molecular Applications Group), MacLook (Molecular Applications Group), BLAST and BLAST2 (NCBI), BLASTN and BLASTX (Altschul *et al.*, 1990), FASTA (Pearson and Lipman, 1988), FASTDB (Brutlag *et al.*, 1990), Catalyst (Molecular Simulations Inc.), Catalyst/SHAPE (Molecular Simulations Inc.), Cerius2.DBAccess (Molecular Simulations Inc.), HypoGen (Molecular Simulations Inc.), Insight II, (Molecular Simulations Inc.), Discover (Molecular Simulations Inc.), CHARMM (Molecular Simulations Inc.), Felix (Molecular Simulations Inc.), DelPhi, (Molecular Simulations Inc.), QuanteMM, (Molecular Simulations Inc.), Homology (Molecular Simulations Inc.), Modeler (Molecular Simulations Inc.), ISIS (Molecular Simulations Inc.), Quanta/Protein Design (Molecular Simulations Inc.), WebLab (Molecular Simulations Inc.), WebLab Diversity Explorer (Molecular Simulations Inc.), Gene Explorer (Molecular Simulations Inc.), SeqFold (Molecular Simulations Inc.), the EMBL/Swissprotein database, the MDL Available Chemicals Directory database, the MDL Drug Data Report data base, the Comprehensive Medicinal Chemistry database, Derwent's World Drug Index database, the BioByteMasterFile database, the Genbank database, and the Genseqn database. Many other programs and data bases would be apparent to one of skill in the art given the present disclosure.

Motifs which may be detected using the above programs include sequences encoding leucine zippers, helix-turn-helix motifs, glycosylation sites, ubiquitination sites, alpha helices, and beta sheets, signal sequences encoding signal peptides which direct the secretion of the encoded proteins, sequences implicated in transcription regulation such as homeoboxes, acidic stretches, enzymatic active sites, substrate binding sites, and enzymatic cleavage sites.

### CONCLUSION

As discussed above, the GENSET polynucleotides and polypeptides of the present invention or fragments thereof can be used for various purposes. The polynucleotides can be used to express recombinant protein for analysis, characterization or therapeutic use; as markers for tissues in which the corresponding protein is preferentially expressed (either constitutively or at a particular stage of tissue differentiation or development or in disease states); as molecular weight markers on Southern gels; as chromosome markers or tags (when labeled) to identify chromosomes

or to map related gene positions; as a reagent (including a labeled reagent) in assays designed to quantitatively determine levels of GENSET expression in biological samples; to compare with endogenous DNA sequences in patients to identify potential genetic disorders; as probes to hybridize and thus discover novel, related DNA sequences; as a source of information to derive

5 PCR primers for genetic fingerprinting; for selecting and making oligomers for attachment to a "gene chip" or other support, including for examination for expression patterns; to raise anti-protein antibodies using DNA immunization techniques; and as an antigen to raise anti-DNA antibodies or elicit another immune response. Where the polynucleotide encodes a protein which binds or potentially binds to another protein (such as, for example, in a receptor-ligand interaction),

10 the polynucleotide can also be used in interaction trap assays (such as, for example, that described in Gyuris *et al.*, (1993) Cell 75:791-803 to identify polynucleotides encoding the other protein with which binding occurs or to identify inhibitors of the binding interaction.

The proteins or polypeptides provided by the present invention can similarly be used in assays to determine biological activity, including in a panel of multiple proteins for high-

15 throughput screening; to raise antibodies or to elicit another immune response; as a reagent (including the labeled reagent) in assays designed to quantitatively determine levels of the protein (or its receptor) in biological fluids; as markers for tissues in which the corresponding protein is preferentially expressed (either constitutively or at a particular stage of tissue differentiation or development or in a disease state); and, of course, to isolate correlative receptors or ligands.

20 Where the protein binds or potentially binds to another protein (such as, for example, in a receptor-ligand interaction), the protein can be used to identify the other protein with which binding occurs or to identify inhibitors of the binding interaction. Proteins involved in these binding interactions can also be used to screen for peptide or small molecule inhibitors or agonists of the binding interaction.

25 Any or all of these research utilities are capable of being developed into reagent grade or kit format for commercialization as research products.

Methods for performing the uses listed above are well known to those skilled in the art. References disclosing such methods include without limitation "Molecular Cloning; A Laboratory Manual", 2d ed., Cole Spring Harbor Laboratory Press, Sambrook, J., E.F. Fritsch and T. Maniatis

30 eds., 1989, and "Methods in Enzymology; Guide to Molecular Cloning Techniques", Academic Press, Berger and Kimmel eds., 1987, which disclosures are hereby incorporated by reference in their entireties.

Although this invention has been described in terms of certain preferred embodiments, other embodiments which will be apparent to those of ordinary skill in the art in view of the

35 disclosure herein are also within the scope of this invention. Accordingly, the scope of the invention is intended to be defined only by reference to the appended claims.

## **EXAMPLES**

### **Example 1: Preparation of Antibody Compositions to the GENSET protein**

Substantially pure protein or polypeptide is isolated from transfected or transformed cells containing an expression vector encoding the GENSET protein or a portion thereof. The concentration of protein in the final preparation is adjusted, for example, by concentration on an Amicon filter device, to the level of a few micrograms/ml. Monoclonal or polyclonal antibody to the protein can then be prepared as follows:

#### **A. Monoclonal Antibody Production by Hybridoma Fusion**

Monoclonal antibody to epitopes in the GENSET protein or a portion thereof can be prepared from murine hybridomas according to the classical method of Kohler and Milstein, (1975) Nature 256:495 or derivative methods thereof. Also see Harlow and Lane. (1988).

Briefly, a mouse is repetitively inoculated with a few micrograms of the GENSET protein, or a portion thereof, over a period of a few weeks. The mouse is then sacrificed, and the antibody producing cells of the spleen isolated. The spleen cells are fused by means of polyethylene glycol with mouse myeloma cells, and the excess unfused cells destroyed by growth of the system on selective media comprising aminopterin (HAT media). The successfully fused cells are diluted and aliquots of the dilution placed in wells of a microtiter plate where growth of the culture is continued. Antibody-producing clones are identified by detection of antibody in the supernatant fluid of the wells by immunoassay procedures, such as ELISA, as originally described by Engvall, (1980) Meth. Enzymol. 70:419, which disclosure is hereby incorporated by reference in its entirety, and derivative methods thereof. Selected positive clones can be expanded and their monoclonal antibody product harvested for use. Detailed procedures for monoclonal antibody production are described in Davis, *et al.* (1986) Section 21-2.

#### **B. Polyclonal Antibody Production by Immunization**

Polyclonal antiserum containing antibodies to heterogeneous epitopes in the GENSET protein or a portion thereof can be prepared by immunizing suitable non-human animal with the GENSET protein or a portion thereof, which can be unmodified or modified to enhance immunogenicity. A suitable non-human animal is preferably a non-human mammal is selected, usually a mouse, rat, rabbit, goat, or horse. Alternatively, a crude preparation which has been enriched for GENSET concentration can be used to generate antibodies. Such proteins, fragments or preparations are introduced into the non-human mammal in the presence of an appropriate adjuvant (e.g. aluminum hydroxide, RIBI, etc.) which is known in the art. In addition the protein, fragment or preparation can be pretreated with an agent which will increase antigenicity, such agents are known in the art and include, for example, methylated bovine serum albumin (mBSA), bovine serum albumin (BSA), Hepatitis B surface antigen, and keyhole limpet hemocyanin (KLH). Serum from the immunized animal is collected, treated and tested according to known procedures. If the serum contains polyclonal antibodies to undesired epitopes, the polyclonal antibodies can be

purified by immunoaffinity chromatography.

Effective polyclonal antibody production is affected by many factors related both to the antigen and the host species. Also, host animals vary in response to site of inoculations and dose, with both inadequate or excessive doses of antigen resulting in low titer antisera. Small doses (ng level) of antigen administered at multiple intradermal sites appears to be most reliable. Techniques for producing and processing polyclonal antisera are known in the art. An effective immunization protocol for rabbits can be found in Vaitukaitis *et al.*, (1971) J. Clin. Endocrinol. Metab. 33:988-991, which disclosure is hereby incorporated by reference in its entirety.

Booster injections can be given at regular intervals, and antiserum harvested when antibody titer thereof, as determined semi-quantitatively, for example, by double immunodiffusion in agar against known concentrations of the antigen, begins to fall. See, for example, Ouchterlony *et al.*, (1973) Chap. 19 in: Handbook of Experimental Immunology D. Wier (ed) Blackwell, which disclosure is hereby incorporated by reference in its entirety. Plateau concentration of antibody is usually in the range of 0.1 to 0.2 mg/ml of serum (about 12 uM). Affinity of the antisera for the antigen is determined by preparing competitive binding curves, as described, for example, by Fisher, (1980) Chap. 42 in: Manual of Clinical Immunology, 2d Ed. (Rose and Friedman, Eds.) Amer. Soc. For Microbiol., Washington, D.C., which disclosure is hereby incorporated by reference in its entirety.

Antibody preparations prepared according to either the monoclonal or the polyclonal protocol are useful in quantitative immunoassays which determine concentrations of antigen-bearing substances in biological samples; they are also used semi-quantitatively or qualitatively to identify the presence of antigen in a biological sample. The antibodies may also be used in therapeutic compositions for killing cells expressing the protein or reducing the levels of the protein in the body.

Figure 1. The effect of the number of trials on the number of correct responses. The number of correct responses was plotted against the number of trials for each condition. The number of correct responses increased with the number of trials for all conditions. The number of correct responses was highest for the condition with the highest number of trials (10 trials) and lowest for the condition with the lowest number of trials (2 trials).

Figure 1. The effect of the number of trials on the number of correct responses. The number of correct responses was plotted against the number of trials for each condition. The number of correct responses increased with the number of trials for all conditions. The number of correct responses was highest for the condition with the highest number of trials (10 trials) and lowest for the condition with the lowest number of trials (2 trials).
